In addition, figurative language is an important tool of creating and sustaining the linguistic identity of food companies. Generally speaking, metaphors are used in business discourse since they facilitate the dialogue between companies and their stakeholders (Bielenia-Grajewska 2009), mainly by relying on well-known concepts to picture novel issues. In the case of the discussed food industry, they turn out to be useful in showing the customer some novelty in alimentation production and processing. Another explanation for the popularity of metaphorical names in corporate communication is the fact that they are remembered easier than standard expressions (Espunya and Zabalbeascoa 2003). As a result, customers are more likely to choose the food product that has the name they know or understand or at least they can easily grasp. Among the different domains used in representing the discussed food industry, the most popular ones include magic, treasury, art, and masterpiece. Showing the food product as mystic, supernatural, or artistic may endow the offered merchandise with the aura of specialty, uniqueness, and prestige – simultaneously stressing efficiency in preparation yet distinctiveness in taste or use.

The most popular adjectives in describing a company include the following: the best, number one, top class, and leading (Bielenia-Grajewska 2012a). These adjectives are used to stress company's strong position on the market or its unique expertise visible in the offered services and products. Certain verbs are also effective in

showing the long-lasting effect of using selected food products. For example, the verbs connected with continuity are used to underline the long-term effects related to nutrition or pleasure, showing that the satisfaction or nourishment is continual, e.g., takes place every day or continues even after one finishes eating the comestibles. The other aspect of using verbs in shaping company identity is connected with the use of tenses. By opting for continual tenses, the link between past and present may be stressed, showing company's role in preserving national cuisine and customer eating habits.

Numbers also convey meaning. For example, they can be used to stress the unique features of the product (e.g., 100% of best ingredients, 100% of satisfied customers). Numbers also play a role in informing customers on people or animals involved in producing the goods. For example, dairy products are advertised by quoting the number of farmers delivering milk or the number of cows involved in milk production. Moreover, numerical features are used to stress the fact that the merchandise is rich in some substance (100% of the recommended dose of magnesium) or low in other elements (only 0.5% fat, 0% color additives).

The other verbal way of creating company identity is by using foreign languages. This linguistic method may serve different functions. On the one hand, foreign languages are used to signal the origin of the offered product or to stress its luxury or uniqueness. For example, French is used in advertising champagne or brie, whereas Italian is employed in promoting mozzarella or pizza. On the other hand, English often serves as the mark of international scopes of company's performance. Thus, campaigns may be conducted in English to reach a considerably vast number of interested stakeholders coming from different cultures. Language issues prove to be especially crucial when the manufacturers want to offer their product on the new markets. The names, slogans, and organizational communication at both the internal and external dimensions should be not only translated but also localized, taking the target culture and its expectations into consideration.

Olfactory Dimension of Company Identity

Olfactory product marketing is an important element of enhancing customers to buy certain products, and consequently, scents are used to stimulate customers' food selection and reinforce subsequent consumption. For example, the smells of merchandise available in the shop are intensified in order to make the client interested in them. This strategy is often used in coffee outlets since customers tend to buy more coffee in the shop after being attracted by its smell. Sometimes food products are used to increase the sales of other goods. For example, the scent of lemon is used in fish restaurants, whereas the scent of grass is supposed to increase the sales of dairy products (Pradeep 2010). Food scents are used in shops to stimulate the purchase by raising some thoughts related to certain memories, holidays, or important dates. For example, chocolate aroma is used for the Valentine's Day (Drobnick 2006) since the exposure to certain ambience is supposed to influence customers' food choices (Stroebele and De Castro 2004). Another example of scent marketing is impregnating the product package with some aroma to disseminate when the package is opened (Wansink et al. 2005). The advertisements of food presented in magazines may also have the pages enriched with some food scent.

Auditory Dimension of Company Identity

Music is part of many daily life activities, including shopping and dining. It has been proved in various studies that the type and volume of sounds influence beverages and food consumption. For example, slow and soft music is used in places where eating is supposed to take long, whereas loud and quick tunes accompany fast meals (Stroebele and De Castro 2004). Music is also used to stimulate some shopping behaviors, including the songs associated with holidays.

The other aspect of auditory identity is related to the sounds produced by food in the process of consumption. For example, the sensory

assessment of crackers takes into account the loudness of sounds created when the cracker is masticated by teeth. To add, the perception of crispness and crunchiness determines the customers' opinions on product quality (Rahman 2009). Moreover, sounds that accompany food preparation may also stimulate food consumption. Sonic marketing is used in some restaurants and bars where customers can not only see but also hear the process of dish preparation.

Tactile Dimension of Company Identity

Apart from the auditory experience, oral-tactile sensations determine one's selection of food products. Tactile texture can be classified into oral-tactile texture, mouth feel features, phase stages in the oral cavity, and tactile experience related to using some object (e.g., utensils) by hands. Thus, such notion as slippery and roughness of food, certain feelings related to the change of the food state in the mouth (burning, hot, astringency), and the geometrical shapes of utensils and sensory hand tactile attributes (fracturability, firmness, spreadability) determine the food selection made by customers (Lawless and Heymann 2010). Customer satisfaction related to food consumption is also connected with the tactile dimension of the environment where the food is served. Consequently, the surface of tables as well as the chair upholstery may determine the satisfaction with the served food.

Channels of Communicating Company Identity in the Food Industry Sector

The aim of a company is to make itself outstanding on the market and to efficiently appeal to potential stakeholders. Thus, the food companies should use both traditional and new media to contact customers and attract potential clients and stakeholders. Taking into account the fact that nowadays face-to-face relations are substituted with distant (even virtual) contacts, companies have to consider other ways of strengthening the relations with customers and

stakeholders. Consequently, the role of Facebook, Twitter, and blogs is becoming more and more popular in the food industry communication. The most outstanding advantage of the new media is the low cost and high speed of addressing a large number of stakeholders. Company identity is, of course, also communicated in conventional media, including advertising campaigns, signs, and promotional events.

Summary

The issue of company identity in the food industry encompasses various notions. To take a broad perspective of the issue that allows for creating and maintaining the effective identity of companies representing food industry, all sensual dimensions have to be examined, paying attention to all spheres of human cognition. At the same time, diversified communicative channels should be used in order to communicate with various stakeholders. Moreover, it should be remembered that the importance of selected characteristics depends on the type of food company and the tools adapted for creating and maintaining company identity should take into account the needs and expectations of diversified groups of stakeholders.

Introduction

Confucianism has more than 2000 years of history and is one of the most important schools of thought in East Asia. Confucius (551–479 BC) is usually considered as the founder of Confucianism, and Mencius (372–289 BC) is the second most important Confucian (the “Second Sage”). After Confucius and Mencius, there are also many Confucians throughout Chinese history. They claim that they are followers of Confucius and Mencius and they develop Confucianism further into a big school. Since Han Dynasty (206 BC–220 AD), Confucianism becomes the official school in China. Although Confucianism originated from China, it has also influenced other regions in East Asia. Confucianism is still one of the main schools of thought in contemporary East Asia such as Japan, South Korea, Taiwan, and Singapore. In Mainland China, Confucianism is rising again after the era of “cultural revolution” (1966–1976). With such a long history and so many Confucians in different periods and regions, “Confucianism” is actually a big name for many diverse thoughts in cultures, literatures, arts, history, and philosophy.

This entry focuses on the philosophy and ethics of Confucianism. Particularly, the Confucian perspectives on animal ethics will be discussed. Although Confucianism does not have a theory of animal ethics, it is not hard to find discussions from Confucians on how we should treat animals. Generally, Confucians suggest humane treatments to animals, but they do not believe that human beings should not eat or use animals. It is possible to develop a Confucian approach to animal ethics, but there is no Confucian approach to animal *rights*. When we compare Confucian perspective with other approaches in animal ethics, such as the caring-based approach, virtue-based approach, interest-based approach, rights-based approach, Kantian-based approach, and contractualist-based approach, we may get a more complete picture of animal ethics in the globe.

This entry begins from discussing humane treatments to animals in Classical (pre-Qin) and Contemporary (Song-Ming) Confucianism. After that, this entry focuses on the Confucian perspectives on eating and using animals. The last part of the entry discusses some comparisons between Confucianism and other moral approaches to animal ethics. Also, please note that I have discussed international animal protection and Confucianism elsewhere (Chan 2015). Some parts of this entry, especially the part of humane treatments to animals and the part of comparisons, are developed and rewritten from that article. Nevertheless, this entry also contains many new points and focuses on the relationship between Confucianism and animal ethics in general.

Confucian Perspectives on Humane Treatments to Animals

Many ancient thoughts in the world do not directly focus on animal ethics, and Confucianism is no exception (Buddhism may be an exception. See the entry “► [Buddhism, Cooking, and Eating](#)” and “► [Buddhist Perspectives on Food and Agricultural Ethics](#)” in this encyclopedia.) Nevertheless, it does not mean that Confucians never discuss the status of animals. This section

discusses why some scholars believe that Confucians support humane treatments to animals.

Confucians support humane treatments to animals, but unlike advocates of interest-based approach, they do not consider “interest” as an important criterion in ethics (e.g., *The Analects* 4.16, *Mencius* 1A1). Instead, they argue for another moral criterion for humane treatments to animals. Although Confucius is the founder of Confucianism, Mencius has a more systematic thought on this issue. To discuss how Confucians support humane treatments to animals, it is better to begin with a famous passage in *Mencius* 1A7.

In *Mencius* 1A7, there is a conversation between Mencius and King Xuan of Qi. The conversation is very long, and so I am going to quote only a part of it here:

Mencius: “I heard the following from Hu He: The King was sitting in the hall. He saw someone passing below, leading an ox. The King noticed this and said, ‘Where is the ox going?’ ‘The blood of the ox is to be used for consecrating a new bell.’ ‘Spare it. I cannot bear to see it shrinking with fear, like an innocent man going to the place of execution.’ ‘In that case should the ceremony be abandoned?’ ‘That is out of the question. Use a lamb instead.’ I wonder if this is true?”

King: “It is.”

Mencius: “The heart behind your action is sufficient to enable you to become a true King. The people all thought that you grudged the expense, but, for my part, I have no doubt that you were moved by pity for the animal. . . It is the way of a benevolent man. You saw the ox but not the lamb. The attitude of a gentleman towards animals is this: once having seen them alive, he cannot bear to see them die, and once having heard their cry, he cannot bear to eat their flesh. That is why the gentleman keeps his distance from the kitchen.” (Lau 2003, pp. 14–17)

A key factor in this story is that the king orders to sacrifice a lamb instead of the ox. Since lamb is cheaper than ox, the king is suspected of being stingy. However, Mencius does not agree with that opinion and defends the king by saying that this is simply a decision based on compassion, i.e., the king cannot bear to see the suffering of the ox.

Compassion is considered as the moral foundation for humane treatments to animals in the Confucian perspective. Indeed, compassion is also considered as the core element in

Confucianism. Mencius believes that compassion is one of the most important essences of humans. As Mencius said in *Mencius* 2A6:

No man is devoid of a heart sensitive to the suffering of others . . . whoever is devoid of the heart of compassion is not human . . . The heart of compassion is the germ of benevolence . . . When these are fully developed, he can tend the whole realm within the Four Seas, but if he fails to develop them, he will not be able even to serve his parents. (Lau 2003, p. 73)

Mencius believes that all human beings should first extend their compassion to the principle of benevolence (*ren*). The second step is to apply *ren* to caring and loving other people, animals, and everything in the world. This idea from Mencius is also the mainstream of thought in Confucianism. Why is compassion such an important moral criterion in Confucianism? An explanation can be found in Contemporary Confucianism.

Contemporary Confucianism is also called “Song-Ming Confucianism,” which means the Confucian thoughts in Song Dynasty (960–1279 A.D.) to Ming Dynasty (1368–1644 A.D.). All Confucians in that period claim that they are followers of Confucius and Mencius. Their major work is to interpret and explain Classical Confucianism further so that Confucianism can successfully reply to some challenges from other schools at that time, such as Buddhism and Daoism. Particularly, Contemporary Confucians aims at developing a Confucian theory of metaphysics and ethics. Although it is out of the scope of this entry to explain every detail of such a Confucian theory, the part of this theory that is related to animal ethics will be discussed below.

Why is compassion or *ren* so important in Confucian ethics? The answer is related to the philosophy of human nature and metaphysics in Confucianism. Contemporary Confucians, such as Zhu Xi and Wang Yangming, believe that since Confucius and Mencius, the mainstream of Confucian thought is that compassion is not only an emotion, but also one of the most important essences of humans (for the works of Zhu Xi and Wang Yangming, see Chan 1963, pp. 588–691, especially pp. 633 & 664–667). The most important virtue, *ren*, is developed from this human essence. A unique thought from them is that they

also argue for “the unity and continuity of the world” based on the importance of compassion and *ren*. This is related to how we should treat animals. Donald Blakeley has a good summary and analysis of such Contemporary Confucian thought:

The Confucian tradition has always placed primary emphasis upon becoming humane (*ren*). Ethical values and moral sensibilities are inculcated in family life and early education. Progress in the cultivation of self and filial conduct expands ideally to embrace standards of propriety in social-political affairs, and these, in turn, are set within and integral to the wider context of nature and the operation of the greater cosmos, that is, “Heaven, Earth, and the myriad things.” When the boundaries of the ethical expand to include all things, the project of cultivating properly the human *dao* must adapt its perspective and range of concerns to that of the greater *dao* (or *tian*, Heaven). (Blakeley 2003, p. 137)

This is a unique view of metaphysics and ethics in Confucianism. Confucians believe in the unity and continuity of nature – from humans, animals, and everything in the world. This explains why compassion is such an important moral criterion. Blakeley argues that a Confucian approach to animal ethics can be developed based upon this unique Confucian thought on metaphysics and ethics. Based on this Confucian thought on metaphysics and ethics, Confucians believe compassion or *ren* is the core virtue in Confucian ethics. Such an idea is elaborated clearly by Mencius, even though it is also widely accepted that Confucius also has such an idea implicitly. Mencius believes that all humans should extend their compassion to the principle of benevolence (*ren*), and then we should have compassion and *ren* to everything in the world, including animals. Therefore, some philosophers argue that Confucians support humane treatments to animals.

Confucian Perspective on Eating and Using Animals

Although some scholars believe that Confucians support humane treatments to animals based on our compassion, other scholars argue that these humane treatments are very limited. They argue that from the Confucian perspective, humans do

not have any obligation not to eat or use animals. They argue that this is because our compassion to humans has a higher priority than our compassion to animals. Confucians at most support limited *animal welfare* only, but they definitely deny *animal rights*. This section explains this perspective in depth.

As mentioned in the last section, Confucians believe in *ren* and extend it to caring and loving other people, animals, and everything in the world. Confucianism is a school of thought that tries to educate and cultivate people from realizing their compassion and benevolence to caring about everything. Nevertheless, it does not mean that everything has equal status in Confucianism. Indeed, when Confucians put human compassion in such a high and unique metaphysical position, it already assumes that humans are more important than animals. Mencius thinks that it is exactly compassion or mind of *ren* that distinguishes humans from animals. Indeed, in his writing, Mencius always compares humans and animals. For example, in Mencius 7A45, Mencius distinguishes caring and benevolence. Mencius thinks that a virtuous man cares about animals but he is not benevolent to animals. He thinks that based on our compassion or *ren*, humans have a higher moral status than animals. If humans do not act based on their compassion, then they will be just like animals. In other words, Mencius believes that humans have a higher hierarchy in morality than animals (e.g., *Mencius* 3A4, 4B19, 4B28, 6A8). Animal rights advocates, on the other hand, believe that humans and animals have the same or similar moral status in accordance with moral criteria such as interest or subject-of-a-life. In short, Confucians and animal advocates have different understanding of the status of animals.

Such a Confucian hierarchical moral status also affects what humans may do to animals. Two applications will be discussed here. First, Confucians never reject the idea that eating meat is morally permissible. Most (if not all) Confucians are not vegetarian (Jiang 2005). Indeed, many passages show that they do not think that eating meat is a moral problem. For example, some passages in *the Analects* say that Confucius does not think that killing animals for food or

hunting is a problem (e.g., *Analects* 7.14, 10.8, 10.9). More importantly, Confucians even believe that food production, including meat production, is morally good when it benefits people. Mencius thinks that it is natural for human beings to enjoy meat (e.g., *Mencius* 1A7, 6A7). Mencius also thinks that a good leader and a good government should introduce policies that make a society not only without starvation but also with food surplus. Mencius also discusses a social policy, which says that a government should make sure that even people in their seventy can have enough meat to eat. For example, in *Mencius* 1A3, Mencius says that “When those who are seventy wear silk and eat meat and the masses are neither cold nor hungry, it is impossible for their prince not to be a true king” (Lau 2003, p. 9). In *Mencius* 1A7, Mencius also has a similar idea to the policy to old people (Lau 2003, p. 23). It is safe to conclude that Mencius would agree to kill animals to prevent famine. Animal rights advocates would disagree with Confucians because Confucians only emphasize our compassion to animals but not the interests of animals. In short, some scholars argue that Confucians suggest that human well-being should have a higher priority than animal well-being. It is not that Confucians do not have compassion to animals. However, Confucians believe in love and caring with distinctions and in accordance with relationships. Therefore, our compassion to humans should have a higher priority than our compassion to animals.

In addition to eating meat, Confucians also believe that it is a moral obligation to sacrifice animals in rituals (*li*). For example, Confucius once criticizes his student Zigong and says that we should love *li* more than animals. As Confucius says in *Analects* 3.17: “Ssu, you are loath to part with the price of the sheep, but I am loath to see the disappearance of the rite” (Lau 1992, p. 25). *Mencius* 1A7, the passage discussed in last section, is also originally about sacrificing that particular ox for *li*. Although the King Xuan of Qi decides to replace the ox by a lamb, he does not abandon the ritual or forbid sacrificing animals. He simply replaces that particular ox because he sees that ox and feels pity for it. Animal rights advocates would strongly

disagree with the King’s decision, but Mencius agrees with the King and defends such a decision. Indeed, in that conversation, Mencius only suggests that a gentleman should keep himself away from slaughterhouse or kitchen. In *Mencius* 1A7, Mencius says “that is why the gentleman keeps his distance from the kitchen” (Lau 2003, p. 17). Also, the major aim of that conversation is not about saving animals. Mencius mainly wants to convince the king to treat people by compassion rather than to argue that one should spare animals from sacrifice. Some scholars argue that this shows that compassion to animals is at most a low level of love in Confucianism, and in this tradition, the sacrificial use of animals in *li* is more important (Fan 2010).

In summary, some believe that one should not exaggerate the idea of humane treatments to animals in Confucianism; at least it is not a view defending *animal rights*. In other words, Confucians only accept a limited caring about animals, but humans do not have any duty not to eat or use animals. Indeed, eating or using animals are not only permissible but even required in some circumstances. It is quite obvious that neither Confucius nor Mencius is a vegetarian. They argue that all governments should try their best to avoid their people from experiencing poverty and famine. It is not a problem to kill animals and eat their meats. In other words, our compassion to human well-being should have a higher priority than animal well-being. In addition, sacrificing animals is necessary for *li*; from the perspectives of Confucius and Mencius, not killing animals for *li* is wrong.

Why Should We Discuss Confucianism in the Debates of Animal Ethics?

Is it necessary to discuss Confucianism in the debates of animal ethics? There are at least two reasons to say yes to this question. The first reason is related to animal ethics in the global world, while the second reason is related to the comparison of different moral theories in animal ethics. This section explains these two reasons in depth.

In such a globalization era, it is nearly impossible to ignore different cultural traditions in the world. Confucianism is an important cultural tradition in East Asia, and hence it is impossible to ignore it completely. This general claim applies to a lot of debates in international issues such as international politics. For example, people discuss how Confucianism contributes to the debates on the universality of human rights (Bell 2006; Chan 2014). When we focus on animal ethics, Confucianism is especially important for some topics in animal ethics. To say the least, if one wishes to promote any approach to animal ethics in East Asia, then it is better to explain how such an approach may face Confucianism.

Let me discuss international animal protection as an example to illustrate the point. Some animal rights advocates, especially those who believe that animals have values in themselves and are not mere tools for humans, argue that we should introduce new international standards and policies for animal protection or modify current international standards and policies (Cochrane 2013; Horta 2013). Such a topic is an interdisciplinary subject between international politics and animal ethics. Some scholars, such as Horta, even argue that the normative foundations to support global justice and human rights can also give us reasons to support international animal protection. In other words, Horta believes that the arguments supporting international animal protection are similar to the arguments supporting human rights (Horta 2013, pp. 373–375. See also Bai 2009). As mentioned above, it is not possible to avoid discussing Confucianism in the debates on human rights. Similarly, we also need to discuss Confucianism in the debates of international animal protection. For example, Confucians emphasize ritual more than law, and they think that one cannot be compelled by legal punishment to be virtuous (e.g., *Analects* 2.3. see Lau 1992, p. 11). They would think that it is better to protect animals based on our compassion (*ren*) rather than our fear of legal punishment (Chan 2015, p. 174). Such an idea can be used in the debates of international animal protection. International animal protection is only one of many topics in animal ethics that is related to Confucianism. Generally,

since Confucianism is a major moral tradition in East Asia, it is worth discussing Confucianism in the debates of animal ethics in the global world.

The second reason is related to the comparison of different moral theories in animal ethics. In the philosophical dimension of animal ethics, one of the most important debates is about the moral status of animals, which is one of the marginal cases in morality. On one side, some scholars argue that animals have moral status. Among them, scholars in the interest-based approach, such as Peter Singer, argue that this is because interest is the moral criterion (Singer 1990). Some other scholars, such as Tom Regan, argue for a “rights-based approach,” which claims that animals have absolute rights and moral status (Regan 1985). On the other side, Kant and contractualist, such as Peter Carruthers, consider that human beings only have indirect duties to animals but they deny that animals have any moral status (Kant 1785/1998; Carruthers 1992). These approaches are considered as traditional approaches in the debates on the moral status of animals.

In addition to these traditional approaches, there are also some other approaches that are not as fully developed as the traditional approaches but still worth for us to consider. Two of them are especially relevant here. The first one is virtue-based approach to animal ethics, which focuses more on how our human virtues affect our attitudes to animals (Hursthouse 2000). The second approach can be called caring-based approach to animal ethics. Although some care ethicists consider that their works do not belong to the feminist tradition (Engster 2006), most care ethicists in animal ethics are feminists as well (Donovan 1990; Noddings 2013). Both feminist and non-feminist versions of caring-approach to animal ethics emphasize the importance of compassion and relationship with animals.

The virtue-based approach and the caring-based approach are relevant here because it is arguably that Confucianism is comparable to them. Scholars discuss and compare Confucianism and virtue ethics, especially how Confucian virtues such as *ren* or *yi* are comparable with virtues in Western virtue ethics (Van Norden

2007). Other scholars also discuss and compare Confucianism and feminism (Li 1994, 2000). One may extend these comparisons to the debates on animal ethics and see how Confucianism contributes to this field. For example, even though Confucianism and feminism are two different moral traditions and have conflicts in many issues, they both emphasize the importance of compassion and relationship with animals. While the feminists focus on the caring characters of female to explain why our compassion and relationship with animals are important to our moral consideration in animal ethics, Confucians provide a unique metaphysical and ethical tradition to enrich the discussion of the importance of compassion and relationship with animals. Some may wonder if it is possible to develop a caring-based approach to animal ethics based on both Confucianism and feminism (Chan 2015), and it is at least interesting to compare the similarities and differences between Confucianism and feminism or virtue ethics in animal ethics.

It is also interesting to compare Confucianism with the traditional approaches mentioned above. It is quite obvious that Confucians do not discuss the moral status of animals in terms of interests or rights. It is also debatable how to compare Confucianism with the traditional Kantian or contractualist-based approach. Kantian and contractualist argue that animals have no moral status, but they also accept that humans have indirect moral duties to animals because of our own virtue or character (Carruthers 1992, pp. 146–169). Based on their unique metaphysical and ethical thought, Confucians think that all things (including animals) have values but not equal values. In such a unique Confucian heritage, humans should humanely treat animals, but it does not imply that humans should not use or eat animals. It is open for debate as to whether Confucian perspective implies direct or indirect moral duties to animals. It is also debatable whether animals have real moral status in Confucian perspective.

It is out of the scope of this entry to evaluate whether a virtue-based or caring-based approach to animal ethics is a more comprehensive moral theory and better than other traditional approaches in animal ethics. It is debatable

whether the virtue-based or caring-based approach, especially the version based on Confucianism, is really an alternative to the other approaches. It is also possible to compare Confucianism with other religions (such as Buddhism) in animal ethics. With all these possibilities, it is safe to conclude that Confucianism can play several roles in the comparison of different moral approaches in animal ethics in the globe.

Summary

In summary, this entry has introduced some Confucian perspectives on animal ethics. On one side, Confucians support humane treatments to animals. On the other side, Confucians also support eating and using animals. Some also believe that a normative approach to animal ethics may be developed based on some ideas in Confucianism. It is open for debate as to whether such a normative approach is better than other approaches in animal ethics. Nevertheless, at least we should realize that Confucianism has a unique perspective in metaphysics and ethics and hence should not avoid discussing it in animal ethics.

Introduction to Conservation Agriculture

Conservation agriculture (CA) reduces soil productivity loss through several practices that minimize the alteration of soil composition and structure, including activities that reduce, change or eliminate soil tillage, and avoid residue burning so as to maintain adequate surface cover throughout the year (ECAAF 2001). The line between conventional farming and CA often blurs as conventional agriculture utilizes many practices typical of CA, such as minimum or no-tillage. However, the conventional farmer believes that tilling the soil is beneficial and would increase tillage if possible, while the conservation farmer questions the necessity of tillage in the first place.

CA maintains a permanent or semipermanent organic soil cover consisting of a growing crop or mulch that physically protects the soil from the elements and feeds soil biota. Zero tillage with

direct seeding is perhaps the best example of CA, since it avoids the disturbance caused by mechanical tillage. A varied crop rotation is also important to avoid disease and pest problems. Some examples of CA techniques include (i) direct sowing/direct drilling/no-tillage, where the soil remains undisturbed from harvest to planting except for nutrient injection; (ii) ridge-till, where the soil remains undisturbed but planting takes place in a seedbed prepared on ridges; (iii) mulch till/reduced tillage/minimum tillage, where the soil is disturbed prior to planting; and (iv) cover crops, where sowing of appropriate species takes place between successive annual crops to prevent soil erosion and to control weeds.

The last several decades have seen rapid advances in the technologies associated with minimum or no-tillage agriculture and their adaptation for nearly all farm sizes, soil and crop types, and climate zones. To date, CA has been implemented on approximately 125 million ha

worldwide (Kassam et al. 2012), but adoption remains slow in some regions (e.g., Africa). As such, there is considerable interest in promoting further CA adoption around the world. To effectively do so, it must first be demonstrated that, for society as a whole, the adoption of the new technology generates net benefits (however defined). While few studies have addressed this broader social welfare aspect of agricultural technologies such as CA, it is often assumed that the net benefits are positive.

Table 1 shows the spatial incidence of benefits from adopting CA. It suggests that there may be a substantial benefit beyond the farm itself for which the farmer may not be compensated. That is, divergences appear to exist between privately appropriable benefits and national or global economic benefits stemming from an expansion of the area under CA. In agriculture sectors around the world, government policy has long sought to address such divides in an effort to boost

Conservation Agriculture: Farmer Adoption and Policy Issues, Table 1 The distribution of benefits and costs associated with conservation agriculture across different

spatial scales (check mark indicates presence of benefit or cost)

Benefits and costs	Incidence at various scales		
	Farm	Regional/ national	Global
Benefits			
Reduction in on-farm costs: savings in time, labor, and mechanized machinery	•		
Increase in soil fertility and moisture retention, resulting in long-term yield increase, decreasing yield variations, and greater food security	•	•	•
Stabilization of soil and protection from erosion leading to reduced downstream sedimentation		•	
Reduction in toxic contamination of surface water and groundwater		•	
More regular river flows, reduced flooding, and the reemergence of dried wells		•	
Recharge of aquifers as a result of better infiltration		•	
Reduction in air pollution resulting from soil tillage machinery		•	•
Reduction of CO ₂ emissions to the atmosphere (carbon sequestration)			•
Conservation of terrestrial and soil-based biodiversity			•
Costs			
Purchase of specialized planting equipment	•		
Short-term pest problems due to the change in crop management	•		
Acquiring of new management skills	•		
Application of additional herbicides	•	•	
Formation and operation of farmers' groups	•	•	
High perceived risk to farmers because of technological uncertainty	•	•	
Development of appropriate technical packages and training programs		•	

Sources: Knowler and Bradshaw (2007)

collective benefits. This situation would appear to similarly invite the promotion of CA by government agencies. However, questions exist around the effectiveness of particular policy approaches and whether CA is sufficiently attractive to farmers and to society in some regions to warrant aggressive government intervention (Giller et al. 2009).

This question is not easily answered. The process of technology adoption at the smallholder level is complex, as demonstrated by the Fig. 1.

Smallholders make choices about technology and resource use under the constraints imposed by their household and on-farm resources, as well as higher level factors at the local to global scales. Information about new technologies and financial conditions is a precursor to changes in farm practices. All these factors affect the net returns, risks, and other pecuniary elements that drive the decision-making process.

In the following sections, the financial and other factors that play upon the adoption of CA

Conservation Agriculture: Farmer Adoption and Policy Issues, Fig. 1 A conceptual framework for studying the adoption of conservation agriculture. (Source: FAO 2001)

and similar technologies by smallholders are reviewed. While financial profitability can be necessary, it is not a sufficient condition for adoption as many studies have shown. More recent research has employed increasingly sophisticated statistical tools to analyze the myriad influences on adoption, and some of this new research is presented here, as well as possibilities to extend research in new directions that include network analysis and social capital. Subsequently, the policy dimension is introduced into the discussion, and the various means of addressing suboptimal rates of CA adoption are discussed, considering both conventional government policy and more novel governance approaches.

Farmer Adoption of Conservation Agriculture

Financial Considerations in Adopting Conservation Agriculture

Since the seminal work of Crosson (1981), numerous financial analyses of conservation tillage have shown that typically it produces higher farm-level net returns than conventional tillage. This is largely true because of reduced costs for machinery, fuel, and labor, combined with unchanged or improved yields over time. Beyond conservation tillage alone, a great number of soil-conserving practices typically produce net financial benefits for adopters, based on meta-analyses of farm-level financial analyses from sub-Saharan Africa and Latin America/Caribbean, as seen in Table 2.

The analysis reveals that for the sub-Saharan African and Latin American/Caribbean regions, on-farm financial analyses of CA-related practices produce a positive net present value (NPV) in a vast majority of analyses, while other conservation practices (non-CA) did so to a lesser degree. More recent research has raised concerns about the private and social attractiveness of CA under specific smallholder conditions, particularly in Africa (Giller et al. 2009). The debate around this point continues to stir controversy and is yet to be resolved.

Other Considerations in Adopting Conservation Agriculture

If it is assumed that the practices associated with conservation agriculture are profitable, then their diffusion among farmers should occur on its own. However, the actual or perceived profitability of conservation agriculture can vary from place to place (Stonehouse 1995), so that there is a need to identify factors beyond just farm-level net returns that explain adoption or non-adoption. There is a long and rich tradition of research that seeks to explain farmers' adoption of particular agricultural innovations. Researchers typically select a number of potential independent variables for inclusion in their analysis based on prior theorizing and test, usually via logistic (logit) or probit regression, to determine which variables correlate with adoption in some statistically significant sense. Factors found to be important in such studies were reviewed by Knowler and Bradshaw (2007), and their findings are summarized below.

Conservation Agriculture: Farmer Adoption and Policy Issues, Table 2 Comparison of financial net present values for conservation agriculture versus other soil and water conservation technologies ($n = 136$)

Technologies	Total analyses	Number with positive NPV	Percent share (%)
Conservation agriculture and related agronomic approaches ^a	40	34	85
Vegetative, structural, and other management improvements ^b	96	55	57
Total, all analyses	136	88	65

Source: FAO (2001)

^aThese practices include (i) field-level agronomic practices that explicitly match the character of conservation agriculture according to FAO (2001) and (ii) farm-level agronomic techniques such as intercropping, contour farming, ridging, or strip cropping that although not formally defined as CA contribute similarly to improved soil condition

^bExamples include shelterbelts, terracing, bunding, and agroforestry

Farmer awareness or perception of soil problems is frequently found to positively correlate with the adoption of soil conservation practices like no-till. More generally, assessments of the presence of conservation attitudes among farmers adopting conservation agriculture have revealed both positive and insignificant correlations. For example, the education level of a farm operator commonly correlates positively with the adoption of conservation agriculture practices; however, some analyses have found education to be an insignificant factor, or even negatively correlated with adoption. The farmer's age has been assessed often, but it is difficult to link to the adoption of conservation agriculture, as with assessments of "experience" that reveal both positive and insignificant correlations.

Assessments of the adoption of conservation tillage and similar soil-conserving practices have often included the biophysical characteristics of the farm itself. For example, it has been hypothesized that owners of larger operations are more willing to invest in new technologies such as direct seed drills. However, empirical studies demonstrate mixed results so that the overall impact of farm size on adoption is inconclusive. With respect to rainfall, similarly mixed results have been found. Some studies have found that the presence of soil erosion and other soil problems on a farm correlates positively with conservation tillage adoption. Related to this finding, various studies have shown that farm operations located within regions of steep slopes and erodible soils have a greater tendency to adopt soil conservation practices, but not always. Indeed, farmer awareness of, and concern for, soil erosion is probably the more critical factor affecting adoption.

Land tenure, farm income/profitability, and labor supply have garnered some attention in studies of conservation agriculture adoption. With respect to tenure, conventional wisdom suggests that owned land is better maintained by farmers than leased land. While some empirical results have supported this hypothesis, other studies have not. With respect to wealth, it is regularly hypothesized that the adoption of conservation agriculture, or indeed any new technology, requires sufficient financial well-being, especially

if new equipment is required. Many analyses that have investigated the role of income and farm profitability on adoption have revealed a positive influence. Complicating this picture is the presence of off-farm activities/income which has been found to have a mixed effect on adoption.

Without knowledge of the practices associated with conservation agriculture via some information or communication channel, adoption is improbable. Indeed, studies of innovation adoption and diffusion have long recognized information as a key variable, and its availability has been found to correlate with adoption. Information becomes especially important as the degree of complexity of the conservation technology increases (Nowak 1987). Government extension programs can do much to provide such information on CA and thereby influence farmers' decisions. As noted earlier, government programs aimed at encouraging the adoption of conservation practices among farmers can be justified by the potential divergence between the narrow interests of individuals and the broader interests of society (Pierce 1996).

In contrast, Lynne (1995) argues that farmer decision-making already reflects a compromise between private and collective utility. Producers often identify this latter interest as "the right thing to do," at least in those places where stewardship is part of the cultural norm. More generally, it has been recognized that individual actions related to the environment may reflect a society's social capital (Pretty and Ward 2001). In the broadest sense, social capital refers to the interconnectedness among individuals in society and considers relationships as a type of asset. Attributes such as "kinship," "connectedness to others," and related social capital characteristics have been argued to influence positively the adoption of conservation technology (Moore and Cisse 2005). Similarly, some analyses have identified membership in producer organizations and other social networks as a positive influence on adoption. Investigations of the role of social capital and networks in conservation technology adoption are increasing, but more needs to be done. More recent analysis of the adoption of broadly defined best management practices places a great emphasis on the role of

agency and local networks of farmers or watershed groups (Baumgart-Getz et al. 2012).

In the end, the meta-analysis study by Knowler and Bradshaw (2007) found that few if any variables introduced into empirical analyses of adoption were found to universally explain adoption in a consistent way. They conclude that “it is possible that researchers have reached a limit in terms of contributing to a refined understanding of the reasons for conservation agriculture adoption” (p. 44). Instead, it is suggested that developing improved site-specific models may be a better avenue of investigation.

Problems and New Approaches in Studying Adoption of Conservation Agriculture

Some key issues arise in studying adoption behavior that have not been considered adequately in previous empirical studies. For example, how do we properly incorporate the constraints that farmers face in managing their operations (i.e., profits are not everything)? Should we be interested in *ex ante* analysis, *ex post* analysis, or both (i.e., most studies are *ex post*, but this has problems)? What about the time dimension (i.e., most studies are cross sectional and consider only a single point in time, whereas adoption is a dynamic process)? How do we explain the extent of CA adopted on a given farm (i.e., most studies only assess adoption versus non-adoption)? When the farmer faces a set of technology choices, how should we model the adoption of a given technology?

Recent analyses address some of these problems cited above but not all of them. For example, Knowler (2005) discusses methods to incorporate nonfinancial constraints in assessing prospects for the adoption of sustainable farming technologies (including CA). He finds that simple trade-off analyses can reveal important information about technology characteristics that may influence adoption by allowing the analyst to eliminate dominated or inferior choices. Duke et al. (2012) used hypothetical scenarios in a discrete choice experiment (DCE) to analyze potential adoption of no-till and several other technologies in Delaware without recourse to an *ex post* analysis of adopters. Similarly, the dynamic nature of

adoption can be assessed using duration modeling developed by engineers to assess failure rates in durable goods. Here, the rate of adoption is modeled using a regression model that relies on introduced variables to explain the observed pattern. Fuglie and Kascak (2001) used duration analysis to study conservation tillage adoption in the USA and found that adoption and diffusion of these technologies has experienced long lags due to differences in land quality, farm size, farmer education, and regional factors.

The addition of more advanced empirical studies and new perspectives in assessing sustainable farming methods is increasing our understanding of the adoption and diffusion of new technologies. But more can be done, as suggested above. For example, most adoption models consider only the “adopt/no adopt” alternatives and ignore how much area is converted to CA. Double hurdle regression models invoke a two-step nested procedure that can estimate first the probability of adopting, then the area converted to CA. Similarly, most adoption models consider a single technology that is either adopted or not, ignoring cases where farmers have choices. As a solution, a multinomial logit model can be used when the dependent variable is a set of non-ordered options and the farmer’s choice from these is regressed against a set of explanatory variables.

Policy and Conservation Agriculture

Conventional Policy Mechanisms to Promote Adoption

Governments around the world, but especially in Europe and North America, have implemented a variety of programs to encourage the adoption of agri-environmental stewardship practices including CA-type practices (see Table 3). Though a variety of mechanisms are available, financial incentives have dominated where conservation is the goal. The rationale for such assistance stems from the perceived and often real divergence between the on-farm and social benefits of conservation.

Assistance can take a variety of forms, such as tax credits on equipment, machine rentals, cost-sharing programs, and direct subsidies.

Conservation Agriculture: Farmer Adoption and Policy Issues, Table 3 A summary of policy approaches to promote agri-environmental stewardship including conservation agriculture

Category	Sample approach
Voluntary compliance	Stewardship agreements, education/extension services, research and development, resource centers, etc.
Economic/trade controls	Cross-compliance requirements, export bans, etc.
Financial incentives	Grants/subsidies, tax rebates, etc.
Regulations	Statutes, fines, zoning, taxes, etc.
Direct ownership/management	Public purchase, trusts, etc.

Source: Pierce (1996)

Assistance is most suitable to help overcome significant initial investments and transition costs and in cases where adoption is unprofitable from the individual farm perspective (McNairn and Mitchell 1992; Uri 1998). However, Nowak (1987) suggests that financial assistance may also be important where the adoption of a technology results in positive net returns for farmers. The author argues that institutional support tends to reduce the risk faced by farmers in adopting an “unknown technology” and thereby reduces their need for detailed information prior to adoption (Nowak 1987). That is, to overcome non-adoption because of onerous information demands, state support is useful. This argument is exemplified by Stonehouse and Bohl (1993), who use a model cash crop farm in southwest Ontario to show that a one-time subsidy covering 20% of outlays would induce a farmer to convert from conventional tillage to no-till.

Instead of merely assessing the impact of one-off interventions for adoption, some analysts have sought to understand how best to promote adoption using a variety of tools in a more targeted way. For example, Uri (1998) identifies a strategy to promote conservation tillage that begins with regional policy makers identifying whether its adoption generally provides a positive or negative net return to potential adopters. Once this uncertainty is addressed, the author recommends education and technical assistance where

conservation is profitable but the farmer is not aware of the technology or its profitability, or does not have the skills to implement it; financial assistance where conservation is not profitable to the individual farmer but would provide substantial public benefits; and regulation and taxes where conservation behavior is required of all farmers, or for those participating in related income support programs (e.g., a cross-compliance measure).

From Government Intervention to Agri-environmental Governance

Alternative policy prescriptions that require less overt or direct state intervention in the agricultural sector have been increasingly identified in the literature. For example, Isham (1999) points out that parallel investment in social capital may help create a sufficiently enabling environment for the adoption of desirable practices, and this may apply strongly in the case of CA. This argument reflects a broader shift in thinking about the role of the state in society. In the agriculture sector, as elsewhere, the role of the state has begun to evolve from one of exercising direct authoritarian control to one of working collaboratively with a diverse array of stakeholders to enable preferred behavior. From a traditionally state-led and technocentric approach to dealing with agri-environmental problems has emerged a more holistic, inclusive, and empowering form of agri-environmental governance. This shift is evidenced in many examples of agri-environmental initiatives wherein participant involvement is no longer mandated from above but rather empowered from below. The Australian Landcare movement serves as a case in point, where complementarities in terms of strengths and capacities of state and community actors are capitalized upon in order to achieve conservation goals on individual properties that create public goods.

In the Canadian context, environmental farm planning has similarly emerged as an alternative approach to achieving collective goals at the individual farm level with modest public transfers. The Environmental Farm Plan (EFP) program began as a pilot project in the early 1990s in the province of Ontario. Developed for farmers by

farmers, the EFP program is a voluntary environmental education and awareness program that engages farmers in a self-assessment of environmental performance, including with respect to soil conservation, and seeks to foster a “duty of care” mentality among producers. The EFP program has been applauded on a number of grounds. In addition to enabling farmer participation in devising and implementing solutions to agri-environmental problems, the EFP program has also been extolled for its bottom-up dimension and learning outcomes. As applied to CA adoption more specifically, this approach would see governments work with civil society organizations and peer associations to create a culture of agri-environmental learning, responsibility, and action, with rewards that mix modest financial assistance with peer recognition and praise.

The “Ecological Goods and Services” Concept

Evidently, this bottom-up “duty of care” approach is not universally regarded as the only or even preferred means of enabling enhanced conservation by individual farmers. The last decade of evolving agri-environmental governance has also seen the emergence of the “ecological goods and services” (EG&S) concept, whereby environmental amenities and qualities stewarded by landowners are recast as commodities for trade (Gutman 2007; Engel et al. 2008). The concept clearly reestablishes the public good nature of agri-environmental stewardship: given that individual landowners or “stewards” are expected to bear the responsibility of meeting heightened standards of environmental protection through additional expenditures or foregone development opportunities, primarily for the benefit of society at large, these landowners must be remunerated by society. Setting questions of farmers’ “duty of care” aside, there are vexing questions of a pragmatic nature that emerge in considering what to pay landowners for the provision of ecological goods and services. How do we differentiate between private and public benefits? How do we value ecological goods and services?

Notwithstanding these challenges, programs for remunerating landowners for the provision of EG&S are proliferating. In Costa Rica, a

nationwide framework of payment for ecological services is supported by the state, in large part through revenues derived from a fossil fuel sales tax. Payments are available to landowners for the provision of water services, biodiversity conservation services, and carbon sequestration services. In Australia, “conservation tenders” are used to encourage and reward the provision of EG&S by landowners through programs like EcoTender and BushTender. Competitive bids are submitted by landowners to undertake an agreed-upon set of management actions in support of particular stewardship objectives. Throughout the world, there are many other examples of programs that reward landowners for the provision of EG&S: the Conservation Reserve Program (CRP) and the Environmental Quality Incentives Program (EQIP) in the USA, the Environmentally Sensitive Areas (ESA) Scheme and the Countryside Stewardship Scheme (CSS) in the UK, and the CAMPFIRE program in Zimbabwe.

A widely referenced Canadian example of rewarding farmers for the provision of EG&S is the Alternative Land Use Services (ALUS) program piloted in the Regional Municipality of Blanshard in Manitoba and in Norfolk County in Ontario and fully implemented in Prince Edward Island. ALUS is a farmer-driven, fee-for-service approach that offers farmers annual payments for the provisioning and enhancement of EG&S. Payments are based on land rental rates and address four landscape features: wetlands, riparian buffers, natural areas, and ecologically sensitive areas. While still in its early stages, emerging assessments point to the potential value of the ALUS approach in enhancing the flow of EG&S to society and in better recognizing and rewarding farmers for the critical role they play as environmental stewards.

While the viability and endurance of different policy and governance approaches to agri-environmental stewardship generally and conservation agriculture more specifically are open to debate, one thing seems evident: the complexity of the adoption process demands a range of approaches. Moreover, a concerted effort is needed to more thoughtfully consider the complementarities among approaches. In the words of

Clark et al. (2007, p. 258), "...we should be wary of the 'one best way' reflex in institutional design." Achieving enhanced conservation agriculture adoption throughout the world will demand ongoing governance innovation among scholars, policy makers, conservation professionals, and the farm community.

Summary

For some years now, various international agencies have promoted a package of soil-enhancing practices under the banner of conservation agriculture (CA), though adoption rates remain low in regions. Many of the associated practices have been employed by farmers and studied by soil scientists for decades. More recently, social scientists have sought to understand the reasons for their adoption (and non-adoption) and the role of government policy in this process. This contribution reviews and synthesizes this area of research to understand better what explains CA adoption and to consider policy implications. The discussion begins with the case for the societal benefits of more sustainable farm technologies such as CA and highlights the arguments for and against this proposition, particularly in the context of smallholders in regions such as Africa. Subsequently, the factors that encourage or inhibit CA adoption are discussed, based on existing studies. A primary finding is that few, if any, universal variables regularly explain the adoption of CA and that efforts to promote CA need to reflect the conditions of particular locales. However, much of this research has not benefited from more advanced statistical and modeling methods, so opportunities for improved analyses in the future are reviewed. Finally, consideration is given to the possibility of enabling CA adoption through targeted policy and broader governance initiatives, most of which reinforce perceived divergences between privately appropriable benefits and societal benefits stemming from an expansion of the area under CA. Whether this perception is justified, enabling further CA adoption globally will require ongoing public contributions, be they in the form of conventional assistance measures or

more novel approaches that remunerate landowners for their provision of ecological goods and services (EG&S).

Conventionalization Hypothesis

Introduction

Organic farming developed rapidly during the 1980s. By the late 1990, some researchers argued

that the growth of organic farming had, in spite of its numerous positive consequences, started to lead to undesirable consequences as well (Buck et al. 1997). These consequences were associated with efforts to incorporate structural elements of conventional agriculture. Scholars worried that in doing so organic farming would change and ultimately lose its alternative character.

Traditional organic agriculture was embedded in a social movement and was even associated with overcoming some traits of capitalist food production, for instance, by emphasizing the social relationship between producer and consumer (decommodification). In contrast Buck et al. (1997) expect the new organic agriculture to be restructured in accordance with the economic imperatives of commodity production. As they put it, agribusiness is entering the field and “finding ways to industrialize organic production” (p. 4). Thus, industrial organic farms introduce methods into organic farming that may follow the legal regulations governing organic farm production, but which are incompatible with organic ideology. Guthman (2004) describes organic mass production as “organic lite.” Hall and Mogyorodý (2001) summarize the conventionalization scenario as follows: “Organic farming is becoming a slightly modified version of modern conventional agriculture, replicating the same history, resulting in many of the same social, technical and economic characteristics” (p. 399).

The groundbreaking article of Buck et al. (1997) sparked an ongoing debate about the empirical and theoretical validity of the conventionalization hypothesis. During that debate, however, the precise meaning of conventionalization has changed. As elaborated below, there are at least three different meanings: first, conventionalization as originally defined by Buck et al., which refers to macro changes in the political economy of organic agriculture; second, conventionalization of microlevel farming practices and farmers’ value base, usually conceptualized as differing attributes of new entrants as opposed to the organic pioneers; and third, conventionalization as a misspecification of modernization processes and consequences of more widespread adoption and diffusion of organic farming.

This entry will first review the conceptualizations of the process termed “conventionalization” and then describe empirical evidence of change in organic production in different countries.

What Is Conventionalization?

Based on an explorative commodity structure analysis of Californian organic agriculture, Buck et al. developed the concept that came to be known as conventionalization. They explicitly linked conventionalization to two important developments in organic farming: Rapid growth and the entry of new market actors: “[E]xplosive growth since the 1980s is both cause and effect of a proliferation of new entrants who are attempting to capture the lucrative niche markets lurking behind organic products and the organic label. Consequently, the field is experiencing rapid changes in production and marketing strategies, and a restructuring of economic imperatives. . . . [A]gribusiness is finding ways to industrialize organic production, a process referred to in this paper as ‘conventionalization’” (Buck et al. 1997, pp. 3–4). The authors identify trends toward conventionalization in discourse, production, and marketing: The introduction of legal regulation of organic farming, emphasizing inputs over processes, in contrast with certification by grassroots-oriented agencies, encourages the participation of larger corporations interested in investing in organic food. Regarding production there are tendencies toward less diversification, with larger farms specializing in the mass production of a low number of high-profit crops, the increased use of migrant labor, changes in land use, and increased contract growing. Closely linked to the latter point are developments in marketing and distribution, resulting in Buck et al. stating that the industry “is beginning to look most like the conventional one” (p. 16). Here, they argue, power moves in the direction of large retailers. In reaction to these trends, more traditional growers may use coping strategies, such as focusing on direct marketing and diversification and emphasizing artisanal production. This may ultimately lead to a bifurcation of organic farming,

with “deep” organic on one side and industrial “organic lite” on the other side. It must be noted, however, that Buck et al. end their paper with a cautious note that their results may represent “individual cases more than clear trends” (p. 16).

Since Buck et al.’s groundbreaking study, the original definition of conventionalization – agribusiness is finding ways to industrialize organic production – has been frequently discussed, debated, and developed by scholars. For example, Coombs and Campbell (1998) point to the regional grounding of conventionalization theory and note that the “case studies have been extrapolated to form theories of change which have been advanced as universally applicable to organic farming in all capitalist societies” (p. 127). Hence, they question whether the concept provided by Buck et al. can be applied in a meaningful way to other countries with different structures of organic markets and of farming in general. In an influential paper on conventionalization, Hall and Mogorodoy (2001) study a number of factors related to farming in Canada, including farm size and specialization, marketing, economic organization, and ideological orientations. They provide an extended operational definition of conventionalization that shifts the level of analysis to the farm(er). Following this operational definition, “conventionalization among producers would be reflected in increases in farm size, changes in the use of marketing channels, and less commitment to organic values and principles” (Padel 2008, p. 64), possibly without the active involvement of agribusiness corporations. This approach captured diffuse concerns shared by many researchers and grassroots activists and paved the way for many empirical studies. At the same time, it diluted the theoretical concept provided by Buck et al. (1997) and changed the meaning of conventionalization.

Padel (2001) interprets these changes in organic farming in connection with Rogers’ (1983) adoption and diffusion theory and thereby provides an alternative explanation of the conventionalization process: The fact that new organic farmers differ from the organic pioneers should not be seen as a threat, but rather as a normal outcome of growth and expansion in the adoption and diffusion process. In the light of this theory,

the “shift in motives, farm and social characteristics among those converting to organic farming is a typical feature of any diffusion process, and not an inherent shortcoming of those currently converting” (Padel 2001, p. 57). Organic farming organizations and advisors should therefore aim at developing information and support for the new adopters that supports the learning process during and after conversion (see also Padel 2008). Similarly, Darnhofer et al. (2010) call for “a more discerning approach to studying change in organic farming” (p. 71). They note that a farming style that is different from that of the organic pioneers does not necessarily undermine organic principles and that change is inherent in organic farming. While some changes in organic farming should rather be seen as professionalization, conventionalization would need to entail a departure from the principles of organic farming.

Empirical Evidence from Different Countries

There have been a large number of empirical studies designed to test the conventionalization hypothesis. Importantly, the initial article by Buck et al. (1997) was an empirical study that developed the theoretical argument based on an analysis of organic farming in California, USA. Using the method of commodity chain analysis on organic farming in New York, USA, Guptil (2009) finds evidence for conventionalization. Industry actors are oriented toward inputs and commodities rather than processes and systems, and they are able to participate in ways that alter the economic landscape for the whole sector. At the same time Guptil identifies a counter trend as cost-price pressures have motivated some farmers to develop the alternative model and adopt farming and marketing practices that emphasize self-reliance and local marketing. Based on a case study of Ontario, Canada, Hall and Mogyorodý (2001) reject the hypothesis of agribusiness entering the organic sector. They do, however, find a tendency among field-crop farmers toward increased farm size, higher mechanization, and specialization on export-oriented produce.

Coombs and Campbell (1998) find that the penetration of organic farming by corporate actors in New Zealand has not led to a dilution of organic standards, but has caused organic agriculture to evolve in two directions: agribusiness relying on export-oriented production and a domestic market supplied by small-scale growers. Similarly, Lockie and Hapin (2005) find polarization in the economic scale of the Australian organic farming and note that the development concurs with only some aspects of the conventionalization hypothesis. Specifically, their evidence suggests that “there has been no conventional takeover of the Australian organic sector – at least not one that is evident in the thinking of organic newcomers. Newcomers and long-standing organic producers have more in common than the bifurcation concept allows. Indeed, both share the same degree of variability in terms of motivations and in terms of farm structure and scale” (p. 304).

De Wit and Verhoog (2007) study organic farming in the Netherlands. They find that influence of conventional commodity chains is increasing and the use of off-farm inputs is high, suggesting that organic agriculture in the Netherlands shows signs of conventionalization. However, they warn that their study “does not provide conclusive evidence for the conventionalization of [organic agriculture] as a whole” due to a lack of sufficient historical data (p. 460). In a study in Germany, Best (2008) finds that newer farms are more specialized and slightly larger than established ones and that there is a growing proportion of farmers who do not share pro-environmental attitudes. Additionally, a small number of very large, highly specialized farms have recently moved toward organic agriculture. However, the vast majority of organic farmers, new and old ones included, show a strong pro-environmental orientation. Zagata (2010) presents a study of values of organic farmers in the Czech Republic. He identifies three groups among new organic farmers: farmers defining organic farming as a way of life, farmers emphasizing organic farming as an alternative to conventional food production, and farmers seeing organic farming as an occupation. Especially the last group shows some contradictory views, but even in this group,

“being organic” is an important part of their self-description. The author emphasizes that business-oriented farmers cannot be seen as conventionalizers and the development of organic farming in the Czech Republic “cannot be reduced to binary categories in terms of a conventionalization thesis” (p. 288).

Evidence from developing countries is limited. Oleofse et al. (2011) report case studies on China, Brazil, and Egypt and find that the newly converted organic farms are business oriented and that their farming systems have not changed substantially during conversion from conventional to organic production. Rather, there is a heavy reliance on input substitution for pest and fertility management. The authors are skeptical about the orientation of the new organic farmers toward agroecology and organic principles. They state, however, that a redesign of the farm system may be a long-term goal for the recently converted farmers and that as of 2011 the organic farmers are not yet embedded in a network of organic producers. Their study provides an interesting contrast to the results of Blanc (2009), who presents a study on organic farming in the rural community of Sao Paulo, Brazil. She observes that there has been rapid growth in the organic sector as well as a broad penetration by actors with strong financial capital. Her assessment of the development of organic farming in the study region is that family farming “may be a way for organic farming to become a development lever for the millions working in Brazilian family agriculture. (...) Organic farming has restored perspectives of working and holding on to land for many families” (p. 331). The different findings of Oleofse et al. and Blanc may be due to that fact that Oleofse et al. study newly organic farms that were isolated and not embedded in networks, whereas Blanc emphasizes collective dynamics, embeddedness, and the complex social process of conversion to organic farming.

Summary

Conventionalization is the idea that features of organic agriculture evolved to mimic those of

conventional farming. There are at least three variations on definitions, depending on whether the focus is on macro structure, farm-level micro perspectives, or the adoption and diffusion of organic farming practices.

The empirical evidence on conventionalization is mixed. The most convincing support for conventionalization, as defined by Buck et al. (1997), comes from the USA. This is not surprising, since the concept was developed based on a case study of organic farming in California. In other regions, however, organic farming is embedded in a different institutional structure and, hence, conventionalization is more difficult to identify. Consequently, the concept of “conventionalization” is important for stimulating the discussion of recent changes in organic farming and for increasing the attention for possibly unwanted developments. It does not, however, provide a conclusive explanation for the development in different economic and cultural settings. At least with regard to microlevel farming practices, the adoption and diffusion process seems to provide a much better explanation of the data for most regions.

Cooking Tools and Techniques: Ethical Issues

Glenn Kuehn

Synonyms

[Cooking technologies](#); [Ethical considerations of cooking techniques](#); [Ethics of cooking](#); [Philosophical implications of cooking tools](#)

Cooking is the oldest of all arts: Adam was born hungry, and every new child, almost before he is actually in the world, utters cries which only his wet nurse’s breast can quiet. Cooking is also of all the arts the one which has done most to advance our civilization, for the needs of the kitchen were what first taught us to use fire, and it is by fire that man has tamed Nature itself. (Brillat-Savarin 1986, p. 217).

Introduction

Cooking technology is noteworthy for ethics because the means and methods of cooking involve a product that is intended to be eaten. Food, by definition, is something to be ingested, and therefore it is to become part of oneself – part of one’s being. This reveals that the ontology of the self and the world are intertwined. While a chair is an object in the world that is (and will

always remain) separated from one's being and "not me," food is an object that is "not yet me." Food's ontology embraces the idea of potentiality, for it is not necessarily always going to be separate from me. Food is the potential me.

Cooking technologies enable one to do things that otherwise would be impossible. Were it not for tongs and long forks, grilling would be unthinkable. Oven mitts make handling hot items and vessels possible. Without a knife, one is reduced to ripping, tearing, and biting. Thus, the tools and technologies of cooking reveal the activities concerning food as involving degrees of interaction of the self with a food item. How one chooses to cook, and with what appliances, reveals the attitudes and values one places on the involvement one has with one's food. When we pick up a bratwurst from the grill and turn it over using tongs, we are operating with an extension of our body. We can "touch and feel" the food, and we are involved in the cooking process. When we use a microwave, in contrast, there is a divorce of the self from the process and a retraction of one's self away from the food. The use of these different tools means something. Ultimately, the implications resulting from these situations reach into personal responsibility, for as the being of the individual is extended through the use of a tool (one's arm is extended through the gripping of tongs), so is one's moral accountability also extended.

The ethics of cooking technology/tool use is currently unexplored. It plays out in the arena of human interaction with/through a food-related environment. The tools, techniques, and instrumental methods which mediate (physically, mentally, emotionally) one's involvement with food are of primary importance in understanding the ethical implications of ethics and cooking.

This arena of consideration is full of potential for future scholarship and discussion. Of particular note will be the investigation of the connection between feminist philosophy and cooking technologies. As tool use in the kitchen has become more and more gadget-oriented, it has (ironically) furthered a class distinction based on gender, resulting in the loss of embodied knowledge by female cooks. Rather than liberating women to

greater levels of equality, cooking technologies have resulted in the further subjugation of women in the context of the kitchen, for what "they" knew how to do by hand can now be done better by a gadget.

Why Food Matters

Philosophically, "food" is a label attached to the huge world of edible items that are then sub-classed into the things one is willing to put in one's mouth and swallow. Said in another way, while a tremendous amount of the natural world is edible, only a small portion of it is labeled "food." The presumption is that "food" is going to benefit one in terms of physical health, resistance to disease, longevity, and general well-being. It's both an ontological and epistemological label that identifies aspects or manifestations of "being" present in the world that one chooses to incorporate into one's individual "being" and items that are deemed appropriate for that assimilation because of the knowledge had about them.

Humans are very selective regarding what they're willing to eat. Food, as an ontological category, is small and relative to a number of factors, including culture, location, time period, personal history, temperament, physiological disposition, allergies, taste, and mood. Very much in play in determining what is and isn't food is the philosophical idea of "seeing as." Itself a combination of ontology and epistemology, "seeing as" is a way of identifying something as part of one's conceptual framework, and as such, understandable in a particular way. To see something "as" food is to see it as not merely edible, but an edible item appropriate to incorporate into one's own body through one's mouth.

To see food as a physiological need is one-dimensional at best. Food is involved in one's ontology on every conceivable level and arena – food becomes the self physically, but also emotionally, spiritually, and mentally – it has influence in social relationships (family, friends, colleagues, public), political relationships, environmental relationships, and the understanding of one's place in the world. It is difficult to find a situation

where food-oriented issues are not relevant. On the most fundamental level, food matters.

Technologies that have to do with one's treatment of food warrant a particular kind of philosophical investigation. That investigation would involve both a careful consideration of the ontological status of food and also great sensitivity to all manners through which the food is treated in its journey to one's body. That examination has yet to be carried out, but it could be, and the intention of this entry is to identify topics that would be involved in that project.

Technology and Ethics

Cooking technology is nestled within the larger arena of technology, and a brief sketch of the history of technology is relevant here. A philosophical understanding of technology focuses on what role it plays in one's life. The locus of this role is not so much on what it is, but on what it does – what is the function of a technology? The primary perspective coming from twentieth-century philosophers is that technology in the form of tools is a means by which one is linked to the world. They are connections and linkages between humans and the so-called “external world.”

In serving as a connecting element, tools can be seen as mediating the experience one has with the objects that are not oneself. One of the significant implications of this view is that the mediation involved through technology influences one's understanding and interpretation of reality. One's perception is through the technology – it is through a telescope that one has a “telescopic” view. This perspective (of seeing technology as a mediating tool use), while certainly not the only philosophical understanding of technology, is one of the most helpful for exploring ethics and cooking technologies.

From this perspective, tools and technological objects are extensions of one's body, but also more than that. Technology not only is a way to connect to, with, and through one's environment but, as John Dewey held, is a way of living in and maneuvering through the world. “Technology”

signifies all the intelligent techniques by which the energies of nature and man are directed and used in satisfaction of human needs; it cannot be limited to a few outer and comparatively mechanical forms” (Dewey 1984, p. 270).

Technology and Ethics: Two Camps

The connections between technology and ethics are strong. As David Kaplan states, “All technologies raise implicit ethical questions. Anything humans make and do is subject to ethical evaluation about appropriate uses, acceptable consequences, and right or wrong actions” (Kaplan 2004, p. 169). This being said, there are two basic camps when it comes to technology and ethics: either one follows the neutrality thesis, where technology is a neutral instrument, offering (in itself) no bias towards positive or negative affect, or one ascribes to the view that all technologies raise ethical questions because they necessarily involve human action and therefore are subject to moral judgment. Kaplan states that “Arguably, technology is itself moral. . . . That would mean that technologies and not just people) are subject to moral evaluation. We could then speak of good-or-bad, right-or-wrong technologies and not just good-or-bad, right-or-wrong human actions” (Kaplan 2004, p. 169).

The distinction could be maintained by considering a wooden spoon. The wooden spoon itself is ethically neutral (for it is simply an object and, on its own, outside of moral consideration), but its use is ethically relevant depending on the context, intention of the user, application, and outcome of using the spoon. While it is debatable whether or not developments in technology, as such, may in themselves embody ethical issues, it is generally accepted that the use of these advances does contain moral and ethical import.

However, this distinction could be seen as simplistic, for it has been argued that technological instruments themselves may embody moral value (Kaplan 2004, p. 169; Verbeek, pp. 232–233). Certainly, technologies direct human behavior and also influence perception of the world. But also, the wooden spoon itself could contain moral

elements which would be ethically relevant. The spoon could be seen as a moral object due to what it is made of, where it came from, how it was created, what it is intended for, and how many resources were used in the creation of the spoon.

One of the most influential philosophical views regarding the ethics of technology comes from Martin Heidegger. Heidegger saw technology as a means of understanding. To see it merely as a means to an end is myopic because the ways in which humans intelligently interact with the world cannot be value-free (Heidegger 1977).

For Heidegger, technology is also inherently problematic, for it is a method of transforming, organizing, and systematizing nature in a way that allows one to view it merely as a resource. While that in itself may not be terrible, the danger involved is that if nature can include humans, then one runs the risk of being viewed as a mere resource as well. Further, since there is neither a comprehensive nor a clear understanding of the world and all its intricacies, efforts at control through technology are, at best, guesses. They are unclear and incomplete interpretations. Kaplan states, “The danger of technology (as *techne*) is that it is a partial and incomplete understanding of being; one that seeks more and more efficiently for its own sake. We interpret everything, including ourselves, as resources to be dealt with as effectively and efficiently as possible” (Kaplan 2004, p. 2).

In the context of cooking, the warnings surrounding technology and efficiency for the sake of efficiency are salient. For example, as the ways in which foods are manufactured and genetically modified to increase not only efficiency in production but also efficacy of taste, the nutritional value of the food often tends to decrease. Further, the regular consumption of hyperefficient foods (notably fast foods) is shown to be detrimental to one’s health and thus act counter to the natural purpose of food itself.

Seeing the technologies involved with food production as being value neutral would be naïve, for the result or “product” of the technology becomes incorporated directly into one’s being. The being of the other is part of one’s future being, and the technological mediation engaged cannot

be free of ethical consideration. Food that causes ill health is dangerous and in some contexts could be seen as the result of immoral technology.

One of the strongest linkages between technology and ethics has to do with intent. As long as technology carries with it the activity of design, and design involves intent/purpose, then an element of normativity is involved in the creation and use of technologies. Objects that are created are created for a purpose. As Bruno Latour states, “...even without explicit moral reflection, technology design is inherently a moral activity. By designing artifacts that will inevitably play a mediating role in people’s actions and experience, thus helping to shape (moral) decisions and practices, designers “materialize morality”; they are “doing ethics by other means”” (Latour 1999, p. 237).

Latour furthers this idea to claim that the artifacts of technology themselves can contain the moral element of intentionality. Technological mediation, he claims, is a form of intentionality, for “...their lack of consciousness does not take away the fact that artifacts can have intentions in the literal sense of the Latin word ‘intendere,’ which means ‘to direct,’ ‘to direct one’s course,’ ‘to direct one’s mind’” (Latour 1999, pp. 232–233).

This view has great implications for cooking and technology, for “doing ethics by other means” implies that the ethics is in the cooking itself. Whether one realizes it or not, one is engaging in moral actions when one cooks, and the moral significance of the act is dependent on which tools are used, how they are used, and why. There would be no such thing as amoral, or morally neutral, cooking.

Cooking Technology and Ethics

When addressing the intersection of cooking, tools, technology, and ethics, a useful goal is to divide types of cooking technologies and tools under common tendencies or characteristics and then investigate the moral implications that arise out of them. A beginning list would include the following:

1. Fire
2. Hand-held linkages
3. Containers and preservation
4. Appliances
5. Fermentation
6. Things one uses to eat “off of” and “with”
7. Kitchen “gadgets”
8. Recipes

Here is a brief consideration of the list. While fire itself isn’t a technology, at its most basic level, cooking is a technological control of fire in various manifestations. Further, the control of heat through cooking is arguably the most significant cooking technology in human history.

Cooking tools involve objects that connect the human body to the food throughout the cooking process – things that extend one’s hands and reachability. This category includes cutting instruments, sticks/spits, stirring things, spatulas, brushes, and tongs.

Containers and methods used to enclose, segregate, prolong, and preserve one’s food all provide an artificial environment for it (even when the elements of that environment are natural). For example, an animal stomach, turtle shell, stone or clay pot, metal bowl, a refrigerator, plastic wrap, and vacuum-sealed bags all provide an environment in which food is held in some state of preservation, suspension, or controlled decay.

The category of appliances includes all machines intended to in some way modify a food-stuff through the application of a form of heat (braise, dry roast, flame, etc.) or physical manipulation. This includes ovens, stoves, grills, toasters, microwaves, bread machines, food processors, blenders, etc.

Related to preservation, fermentation is a “natural” occurring cooking method that can be controlled and augmented by human intervention.

Things used to eat off of/with include all of the instruments used to bring a food item to one’s mouth: plates, dinnerware, forks, glasses, spoons, etc.

Somewhere between linkages, containers, and appliances are kitchen gadgets. These are items that are intended to make the food preparation process easier and less dangerous. Items such as

choppers, garlic peelers/presses, food mills, and cherry pitters fill this category.

Finally, recipes hold an ontological status similar to a written piece of music. In itself it is not the food (just as the score is not the music), but instead is one of the means through which the product is created, directed, understood, and enjoyed. It may not be necessary, but it is often quite helpful. A recipe also has significance for historical, cultural, religious, and literary consideration.

The categories of fire and appliances are explored below.

Fire

While creating instruments (crude knives, spears, etc.) with the intent to kill an animal in order to eat it is one of the first food-related technologies that most clearly brings ethics into eating, it was cooking itself that had the most impact on humans’ moral relationship with food. This is because cooked food opens up the natural world to humans as eaters and presents far more of it (in both plant and animal form) as digestible.

Prior to cooking, humans were limited not only to what could be found and eaten on the spot but also to what was easily digestible: berries, nuts, fruit, and a rather limited amount of protein – most likely in the form of insects. Cooking allowed objects in the world to become more available to humans as eating options, for more grains and plants could become digestible, as well as meats which, prior to the control of fire, had to be eaten raw. Ethically, this opened up two big arenas for humans: energy distribution (and therefore individual direction of human lives and goals) and ontology.

First, regarding energy distribution, prior to cooking, the energy gained through eating was spent primarily on immediate refueling of the energy spent on finding the food. After cooking, eating energy was directed more towards the brain and other functions that were not immediately involved with survival. What cooked food provided was a shift in how humans spent their energy. Whereas a tremendous amount of it was also previously spent on digestion (it takes a lot to process raw food), it could now be freed up for use

by the brain (which grew larger) on other projects. Richard Wrangham notes:

The extra energy gave the first cooks biological advantages. . . . They survived and reproduced better than before. Their genes spread. Their bodies responded by biologically adapting to cooked food, shaped by natural selection to take maximum advantage of the new diet. There were changes in anatomy, physiology, ecology, life history, psychology and society. (Wrangham 2009)

Second, western philosophy has been dealing with a 2000+ year hangover regarding subject/object, self/other, and theory/practice dualisms that boil down to the distinction between the “me” and the “not me.” Ontologically speaking, food occupies a unique position in the so-called external world for it is unlike the average rock, tree, clouds, oceans, and even fire. All of these “things” are regarded as the “not me.” Food, on the other hand, is something that is, by definition, an object that is going to be assimilated into me, and therefore is the “not yet me.”

Food’s ontological status is one of potentiality – it is the potential self. The range of objects in the world that one is willing to label as “food” denotes also the range of objects that one is willing to put into one’s mouth and accept into one’s being. The intimacy of the relationship humans have with food is therefore quite profound, and the ethical implications of what is called “food” are far reaching. The often-quoted line from Jean-Anthelme Brillat-Savarin, “Tell me what you eat, and I shall tell you what you are,” points both to the profound meaning in eating and to the fecund moral implications of eating.

With the gain of control over fire and its use, the realm of the “not me” got smaller and the “not yet me” became larger. With the expansion of the category of things now available as food, also came the expansion of the self and of one’s identity.

Appliances

The use of cooking appliances reveals levels of interaction and involvement that one is willing to have with food, but also, various appliances highlight epistemological issues regarding the knowledge required to cook in certain ways. Without the knowledge of how to cook something “by hand,”

there is a reliance on technology in the form of appliances to “do it for us.” Thus, it is often found that there is a removal of the self from the cooking situation. This could carry with it an attempted abdication of responsibility. Further, the use of some appliances highlights the “mere product” perspective on food.

Consider the basic differences between making bread by hand and making bread in a bread machine. There is an embodied, tactile knowledge that comes from kneading bread, baking techniques, utilizing different types of yeast, and so forth. There is also a degree of knowledge that comes from using a bread machine – but it reveals something quite different from making bread by hand. Making bread by hand depicts a continuum of bodily meaning throughout the entire process, culminating in the finished loaf. The bread machine creates the bread without the user of the machine having to know much about what it takes to make bread. The bread machine is a near equivalent to taking the industrial process of making bread, in which one does not participate, right into one’s own kitchen. The bread machine reminds one of a disconnection from the process that produces the bread eaten, even as it pretends to connect one to it. The emphasis on “not doing” it ourselves allows one to relinquish responsibility for the food produced. Clearly, even though some individual put all the ingredients into the bread machine and turned it on, the machine “made” the bread, and the resulting bread is not the responsibility of the individual.

Avoiding interactive, tactile bread-making processes such as kneading, rising, punching, and shaping reveals a split between means and ends and places value solely on the ends. The bread machine does not remove one from the cooking context entirely, because cooking is still happening. However, it alters the context such that one is no longer participating directly in the cooking – the cooking is happening without one’s involvement. In this case, the bread machine bread is presented primarily as an object of consumption instead of the culmination of an interactive and meaningful process. Albert Borgmann notes that devices that do the work for us have divorced us from meaningful practices involving food and that

the experience of dining together has been offset by grazing and “grabbing a bite to eat” (Borgmann 1995, p. 90).

Borgmann points to an important aspect of experience which is being devalued by the use of certain technological advances. The use of something such as the bread machine is not merely an instance of unburdening, efficiency, or convenience. It indicates something much deeper in the experience in that the use of something such as a bread machine does not offer an enriched level of involvement with the process of cooking. There is experience, but it is disconnected or disjointed from the continuum of interactive meaning that comes from engaging one’s environment.

One might wish to object to the severity of the above claims by comparing the bread machine and its task to another appliance such as an oven, which itself “cooks” the bread, turkey, potato, or cheesecake. But the oven really only accomplishes one task in the cooking continuum: it heats stuff. The bread machine is different because it is a multitasking appliance that mixes, kneads, controls the rising, and bakes the bread; it does not merely do all the work, it does all the work without the involvement of the skill, technique, or knowledge it takes to make bread. The machine does not have knowledge, it bypasses it. The oven is part of the overall process, the final stage, of baking the bread – which is also something that we cannot do ourselves, thus further distinguishing the use of the oven from the use of the bread machine. The bread machine can be used to bypass the process of making bread almost entirely. Therefore, with the bread machine the emphasis is on the product, and this emphasis becomes morally problematic because the bread machine replaces us and our actions and decisions.

Suggestions for Future Work

For Dewey, however, tools do not have the last say. Instead, technological innovations tend to rearrange existing alliances, tip balances of power, render some forms of community life obsolete, and encourage the development of others. (Hickman 2001, p. 216).

Technology both keeps up with and drives human culture. The topics to consider and pay attention to as cooking technologies and tools continue to develop are difficult to predict with assurity, but there are some areas which warrant special attention.

Of particular salience is the intersection of gender, cooking practices, equality, and technology. This convergence points to a need for a strong voice from feminist philosophers. This has already begun in the context of technology and gender equality, and the extension of it into cooking practices (and into food and agriculture as a whole) is a logical next step. Corlann Gee Bush has begun this dialogue by showing that societies that have established divisions of labor based upon gender also have differing technological effects on men and women. What happens is that the technologies tend to reinforce patterns of gender inequality already established within that culture (Bush 1983).

For example, “tech fixes” (new, quick, technological advances designed to solve problems, aka, “gadgets”), while superficially useful and morally harmless, ethically backfire in that they perpetuate a class divisions based on epistemological suppression. If groups (based on race or gender) are associated with the traditional tasks that have been “fixed” by the technology, then that class’ subjugation is further established.

Underlying the motivation of a tech fix is the idea that technology will provide all the solutions needed to ameliorate one’s troubles. So, where there is a widespread inability to utilize a knife in the context of a kitchen for chopping, dicing, etc., there are gadgets (tech fixes) that do the work for you and produce the “exact” same result as though the food were chopped by a home cook who knows how to use a knife. Rather than provide liberation, the tech fix ends up supporting traditional gender inequality (and perhaps make it worse) by further removing the (usually female) cook from the process of cooking and showing that she is intellectually incapable of figuring out how to chop an onion on her own with a knife. She needs an enclosed, plastic chopper to do it for her – all she has to do is hit it.

One could easily see the original encroachment of the tech fix into cooking through the first wave of TV dinners which showed female cooks that machines in factories far away were capable of cooking better, more efficiently, and more conveniently than she was able to do at home.

Summary

This entry provides an overview of some connections between cooking, technology, tool use, and ethics. This intersection has yet to be explored philosophically, and the author highlights several of the salient issues that arise in this context.

Introduction

Globalization refers to the movement of people, things, ideas, and capital across the world as well as the processes and structures that enable this circulation, the ideologies intertwined with it, and the resulting circumstances (Murray 2006; Mittelman 2004). Globalization entails an interdependence that affects many aspects of life for individuals in distant but nevertheless connected locales. A drought in one place may result in a dramatic rise in food prices, the implementation of export restrictions, and the occurrence of riots in other places. Globalization's impact on food production, marketing, distribution, preparation, and consumption abounds with ethical implications. Energy policies, economic subsidies, and other politico-economic factors influence what and how people across the world eat. What consumers in one part of the world

purchase, in turn, affects societies that produce foodstuffs for global consumption (Mintz 1985). This introduction describes the globalization of food and agriculture in historical context, while subsequent sections examine ethical implications in greater depth.

Globalization did not begin at any particular time. Human migration across the globe, colonialism, and the spread of neoliberal economic ideas that has occurred since the late 1970s are events that have significantly shaped human interaction across the planet. Important events in the globalization of food that have affected the eating patterns of human societies across the world include the spread of agriculture and domesticated plant and animal varieties across continents and the establishment of major trade routes such as the Silk Road in the second century CE. The Green Revolution, the process by which agricultural production increased exponentially in the mid- to late twentieth century as a result of the development and use of chemical fertilizers and pesticides, F1 hybrid crop varieties, irrigation techniques, and so forth, is another significant event.

Although globalization is not a new phenomenon, the current phase of globalization stands out in terms of the scale, reach, and speed at which movement across great distances takes place. Economists now calculate the daily turnover in financial markets at the scale of trillions of US dollars. Technological developments in transportation, communication, and information technology in the latter part of the twentieth century have led to a world that is more interconnected than ever before, albeit unevenly. International trade has expanded significantly over the past 50 years (Bruinsma 2003). New refrigeration technologies permit many perishable goods to be transported across continents without being frozen or processed.

The current phase of globalization is also notable for the prevalence, influence, and reach of transnational corporations. A-B InBev, for example, is headquartered in Belgium but has a workforce of 100,000 in 30 different countries. Many of its recent Executive Board of Management members have been Brazilian, but there have also been Portuguese, American, and

Indian-German members. Its beers – from Budweiser, Beck’s, and Stella Artois to Harbin, Brahma, and Bass – hold the number one or two slots in 19 key markets and have captured more than half of the market share in Belgium, nearly half of the US market, three quarters in Argentina, and almost the same percent in Brazil (A-B InBev 2011).

Globalization entails the circulation of capital, goods, individuals, and ideas across the world. Institutions such as the World Trade Organization (WTO), the World Bank, and the International Monetary Fund (IMF) have promoted the liberalization of markets, the creation of international trade regulations, and the establishment of free trade agreements, though these have encountered opposition from activists and interest groups across the world. The liberalization of labor markets and the free movement of people across the globe have not been promoted in a similar fashion. In spite of this, people move around the world today in increasing numbers, to increasingly distant places, at unprecedented speeds. Many migrants find employment in the food industry, particularly in developed economies. Celebrity chefs like Jamie Oliver, Madhur Jaffrey, and Nobu Matsuhisa have appeal beyond their countries of birth. Less advantaged individuals may work on farms, in meat processing plants, and in kitchens. Tourists also travel across the globe, coming into contact with unfamiliar foodstuffs, dishes, cuisines, and foodways. The term “culinary tourism” refers to the industry that has emerged to cater to those who seek out gastronomic experiences in faraway places. Ideas have circulated the globe along with people, things, and capital. Neoliberal economic policies are especially noteworthy for their recent influence across the globe. The increased interconnectedness of distant locales via new technologies and social media has also made it possible to share knowledge about cooking techniques, management practices, and nutritional information. Globalization has also facilitated the organization of movements like the Christian hunger relief organization Bread for the World, the Worldwide Opportunities on Organic Farms (WWOOF) movement, and anti-WTO protests.

Although globalization has to do with circulation, not all places are equally connected to the flow of people, ideas, things, and capital. Famines, undernourishment, and food deserts are also aspects of globalization. These phenomena demonstrate that globalization is not transforming the globe into a homogeneous and equally resourced place. In the following sections, this entry will examine the ethical implications of the globalization of food and agriculture in terms of contemporary concerns about its impact upon economic systems, human health, cultural diversity, the environment, as well as democracy and the agency of disadvantaged groups.

Economics

Globalization is often equated with neoliberalism – a set of economic beliefs and policy proposals centered on deregulation, privatization, and pared-down state budgets for social programs. At the global level, neoliberalism emphasizes the liberalization of world markets and the implementation of “free trade.” In the latter half of the twentieth century, neoliberalism gained popularity with economists and policymakers the world over. A comprehensive transnational agreement eliminating subsidies and tariffs is lacking for agriculture and food. In spite of this, food prices have declined in real terms since the Second World War. In 2008, however, in what analysts and the media have termed a “global food crisis,” food prices rose dramatically in much of the developing world, creating a great deal of insecurity and stimulating food riots. As of 2012 prices have stayed high compared with earlier decades. Possible contributing factors include bad harvests for major producers, a reversed trend away from overproduction, and financial speculation in agricultural markets.

There are ethical motivations at the heart of free trade theory. Advocates argue that the liberalization of agricultural markets and the expansion of free trade would result in more efficient economies, savings for taxpayers and consumers, and benefits for countries in the developing world. The Organization for Economic Cooperation and

Development (OECD), for example, holds that “simultaneous reform involving a halving of trade protection and domestic support across all sectors could potentially generate USD 44 billion in welfare gains globally. Most of these gains arise from agricultural reform and most of these agricultural gains come from reform of market access measures” (OECD 2006).

One criticism of the world trade system established under the WTO is that it hurts developing economies. Developed economies distribute substantial subsidies to farmers who subsequently “dump” commodities on global markets at artificially low prices with which farmers in developing economies cannot compete. Agricultural trade has grown much more slowly over the past half-century than has the trade in manufactured goods (Bruinsma 2003). On average, tariffs on agricultural commodities are as high as industrial tariffs were in 1950. As a result, developing countries have become net agricultural importers, with the situation most dramatic in the least developed countries. If current trends hold, the Food and Agriculture Organization (FAO) of the United Nations estimates, by 2030, developing countries will reach a level of net imports of USD 31 billion. FAO analysts deem it probable that developing countries will import greater and greater quantities of food from developed countries while exporting larger amounts of agricultural products such as beverages, fiber, and rubber (Bruinsma 2003).

Ethical criticisms of free trade often focus on exploitative labor practices, wealth disparities, environmental degradation, and other negative conditions that may result from deregulation and trade liberalization. Movements and organizations such as the “trade justice” movement and the international nonprofit organization Fairtrade seek to alleviate harsh and exploitative labor conditions and ensure that more of the money paid for commodities from the developing economies, such as bananas and coffee, may actually reach those who produce them. Focusing on the power of consumer action, the Fairtrade model employs certification and labeling meant to distinguish agricultural and craft goods whose producers receive adequate compensation for labor they

perform under conditions that are socially acceptable from those who do not. Today, the Fairtrade foundation is responsible for billions of pounds in sales in the United Kingdom alone. Fairtrade and its model, however, have come under fire for being ineffective, untransparent, deceptive, and even harmful to farmers who do not participate (Griffiths 2012). The ability of consumers to ascertain that their purchases of foodstuffs from distant places contribute positively to the lives of those who produce them is thus questionable.

Health

Globalization has had positive and negative impacts on people's diets, resulting in a range of health consequences. The circulation of foodstuffs, including perishable commodities, across long distances means that many societies today have access to a variety of nutritious foods. Crucially, fruit and vegetable availability has increased since the 1960s across the world (Mendez and Popkin 2004). As a result, nutritional status has improved since the 1960s, with the important exception of sub-Saharan Africa.

While the availability of foods from distant places enables some groups to diversify their diets, it can also threaten local foodways. Those who are less well-off often find they can no longer afford traditional foodstuffs after they have been turned into export crops and may have a difficult time finding acceptable alternatives. Quinoa, for instance, has long served as a source of nutrition for many Bolivians. In the late twentieth century, global demand for the crop surged, primarily because of increased consumption by the North American and European middle class. Though Bolivian farmers' incomes improved as a result, lower-income groups could not sustain prior consumption patterns for this healthy traditional foodstuff because of the degree to which prices had risen.

Recent trends toward dietary convergence show increased consumption of sugar, salt, fat, and vegetable oil, and a decrease in dietary fiber intake (Kennedy et al. 2004). Indeed, the dramatic increase in obesity rates across the world,

especially for children and particularly in Pacific Island nations, is believed to be at least in part the result of the tremendous growth in worldwide consumption of processed and high-calorie-content foods, including fast-food chicken, instant ramen, and soft drinks (World Health Organization Regional Office for the Western Pacific 2002; Sobal and MacIntosh 2009). This is worrisome considering links between obesity and high rates of heart disease, diabetes, hypertension, and other health complications, as well as the complexity of addressing the double burden of both undernourishment and overnourishment in developing countries. The World Health Organization has proclaimed a global obesity epidemic and along with state governments, and nongovernmental organizations, and other international institutions, it is attempting to address the problem.

The flow of food and knowledge across the world does not reach all people in the same ways. Many multinational organizations and nongovernmental organizations work globally to spread nutritional knowledge – from the benefits of breastfeeding to notions of a “balanced” diet, alleviate food crises, and prevent future ones from occurring. Yet hunger and undernourishment persist despite sufficient global food production (Sen 1981). Famines have social causes as well as environmental and economic ones and increasing production will not eradicate famines or undernutrition. Indeed, global food production measures approximately four billion tons, but the FAO calculates that about a third of that food is never consumed (Gustavsson et al. 2011). “Food loss” refers to the decrease in food mass that occurs during the stages of agricultural production, post-harvest handling, storage, and processing. “Food waste,” meanwhile, is applied to similar losses that take place during distribution, retail, and finally individual and group consumption. As these definitions indicate, food loss and waste occur at every point in the food supply chain. The FAO estimates a level of annual per capita food loss and waste of 6–11 kg of food in sub-Saharan Africa and South and Southeast Asian countries, in contrast to a much higher level of 95–115 kg in Europe and North America. Overconsumption may also be categorized as food

waste that has negative repercussions for human health and the human ecological footprint (Blair and Sobal 2006). The inequalities perpetuated in the global food system are striking when one considers that 870 million people are chronically undernourished while billions of tons of food goes unconsumed and many individuals consume far more food than their bodies require (FAO, WFP and IFAD 2012).

Culture

Culture permeates every aspect of the global food supply chain. Even the forging of global agreements concerning food safety via international institutions is complicated by cultural differences over how a food product's safety is determined and to what extent items such as unpasteurized cheese, hormones in meat, and genetically modified (GM) foods can be deemed safe (Korthals 2004). One ethical concern evident in discussions about the globalization of food, cooking, and cuisine is that the contemporary processes of globalization are replacing the world's vast food cultures with a heterogeneous food culture originating in the West and in particular the United States. The term "McDonaldization" is often used to represent this perspective (Ritzer 1993). Indeed, the Slow Food movement was catalyzed by the construction of a McDonald's near the Spanish Steps in Rome. French farmer Jose Bove grabbed global headlines when, as a sign of protest against globalization, he led a movement to take a McDonald's apart before it could open. The argument that mainstream American culture – epitomized by McDonald's – is engaging in a kind of cultural imperialism is of ethical concern because it highlights threats to the agency and self-determination of disadvantaged groups (see section below on Democracy and Agency) and decreases in the richness of human cultural diversity. While American corporations such as McDonald's, Doctor's Associates, and Yum! Foods do dominate the global market for fast food in terms of market share, they are not necessarily engines of cultural homogeneity. Indeed, McDonald's franchises adapt to the places they are situated. Thus, McDonald's franchises in

Mumbai, Kyoto, Santa Monica, Paris, and Moscow vary considerably in terms of menu, store design, and how customers use them (Watson 2006). The international spread of fast-food ventures is also not a simple cultural shift but related to factors that include trends such as urbanization and women working outside of the domestic sphere.

The circulation of foods across the globe has never been a unidirectional process (Plotnicov and Scaglione 1999). For instance, the establishment of trade routes and colonies that followed explorer Christopher Columbus's arrival in the Caribbean spurred the movement of people, plants, animals, diseases, and ideas across continents. This transformational event has been called the "Columbian exchange" (Crosby 1972). Though neither free nor fair, these exchanges brought cattle, citrus, and wheat to the Americas and corn, potatoes, and tomatoes to Europe. Spicy Korean cuisine, Italian marinara sauce, and Colombian coffee did not exist prior to this event.

The diffusion of foodstuffs, dishes, and cuisines has also been evident in more recent years. Dishes such as curry, fried rice, French fries, pizza, sushi, guacamole, and croissants are now commonly found in many countries. Water is bottled, branded, transported across the world, and consumed in places with abundant resources of their own. Restaurant menus as well as domestic fare demonstrate an international influence and a tendency toward adaptation and creolization.

Though globalization has not resulted in a uniform cuisine, certain trends have had a great deal of influence upon foodways across the globe. In the recent phase of globalization, the image of a "modern" city is one that is cosmopolitan enough for residents to eat in Ethiopian and Vietnamese restaurants, shop in Mexican and Chinese grocery stores, and browse in bookstores that carry Indian and Spanish cookbooks. Elites eat luxury foods like vintage wines, caviar, Kobe beef, and French cuisine, develop a familiarity with various "ethnic" cuisines, and adopt self-imposed food restrictions as in veganism, locavorism, or special diets. Markers of status such as these are sought after and derive their value directly from the difficulty required to obtain them, clear indications of inequalities in the global food system.

Technological advances in communication have facilitated the emergence of organizations like Slow Food International that have had a great deal of influence on the global discourse of food, cuisine, and ethics. Founded in Rome, Italy, in the late 1980s, Slow Food now claims to have 100,000 members in over 150 countries. Its aims include the safeguarding of local agricultural and culinary traditions and the promotion of sustainable farming. Critics of the Slow Food movement view it as elitist, antiscientific, anti-change, and ignorant of the challenges involved in producing and preparing food to feed whole societies.

As migrants and tourists move across the globe, individuals and societies experience culinary traditions new to them. Such interaction can generate an understanding of specific food cultures and form the basis for respecting cultural differences. Though culinary tourism and the consumption of “ethnic” foods appear to sustain traditional foodways, they also engender change. New standards for what is authentic and what is desirable are established, with tourists and foreign food experts often imposing their judgments and consequently altering local food culture in the process. Although Asian cuisines have gained a great deal of popularity in recent years, for instance, whale meat and dog meat have been met with disapproval from many tourists and travelers and are now consumed far less frequently than they once were.

The Environment

One consequence of the dietary convergence that has accompanied globalization has been a loss of biodiversity. Rice, wheat, and maize have become the dominant grains, though the varieties of even these crops have also decreased. The decrease in global biodiversity is also the result of climate change, habitat change, the introduction of invasive species, overexploitation, and pollution, which all may be linked to globalization as well. The overexploitation of natural resources including marine fisheries continues to threaten global biodiversity (Bodiguel et al. 2009). Decreases in

biodiversity render areas engaged in large-scale monocropping vulnerable when unfavorable ecological conditions, from drought to pestilence, develop. They can also negatively impact the health of local societies and cause cultural, economic, and social dislocation. The mid-nineteenth century Irish Potato Famine is a stark example of this.

Neoliberal economists and many state actors promote an industrial agricultural model characterized by large-scale monocropping. Such agriculture is fuel dependent and releases greenhouse gases (GHGs) into the atmosphere, contributing to global climate change. Importantly, the countries responsible for the largest GHG emissions are not those that suffer the consequences the most. Thus, although the United States and the People’s Republic of China release the greatest amounts of GHGs, it is nations such as Kiribati and the Marshall Islands that experience existential threats as a result. The purchase of industrial agricultural foodstuffs sustains such a model and contributes to the human ecological footprint. Food travels great distances – often thousands of kilometers – before it reaches consumers and a food item’s provenance is easier to identify than the environmental impact involved in producing and transporting it. In this context, the notion of “food miles,” the measurement of the distance a food has traveled from place of production to the place the consumer procures it, is used to index its environmental impact and specifically the greenhouse gas emissions accrued throughout the supply chain. Calculating the contribution of discrete consumer purchases to the climate footprint in “food miles” has generated criticism because it omits the much greater amount of GHG emissions related to food production, resulting in a misleading view that foods that are produced locally have less impact upon the environment than those transported from more distant places (Weber and Matthews 2008). Consumers purchasing food on the basis of “food miles” may not only misunderstand the extent of their food’s climate footprint, but by declining to buy foodstuffs that have traveled great distances, they may actually hurt producers in developing countries that are low emitters of greenhouse gases.

Large-scale farming for global markets may also contribute to environmental destruction that exacerbates other problems. This is the case with shrimp farming in places such as Thailand and India. Though they provide employment and bring economic benefits to the areas where they are located, shrimp farms are linked to pollution, the cutting off of communities from access to local resources, and the destruction of mangroves, which leaves local populations more vulnerable to natural disasters like tsunamis and cyclones.

While the negative environmental consequences of the globalization of food are prominent, there have also been positive ecological developments that are linked to globalization. The sense of global awareness of transnational environmental problems such as climate change and the participation of state and non-state actors (including civil society) in trying to come up with measures – from treaties to new technologies – to address them is one positive development. The recent popularity of self-consciously “organic” farming and its products is one movement worth noting, though the term has been criticized for being ill-defined, used in ways that both lack transparency and established international standards.

“Local” food movements have emerged across the globe often as a reaction against the negative aspects of a global food system. Yet these are also a result of the processes of globalization that facilitate the flow of knowledge about food systems, the ideals behind local food movements, and the various means of creating localized food systems. These movements include community-supported agriculture (CSA) groups, areas seeking to be food self-sufficient, and farmers’ markets and other means whereby farmers sell their products directly to consumers. Critics of local food movements identify xenophobic tendencies and the creation of boundaries that can have negative consequences for those excluded. Because what is considered “local” is not defined in many instances, the term is susceptible to overuse by marketers, resulting in a situation whereby local agriculture neither necessarily refers to a specific proximity between producers and consumers nor entails the implementation of environmentally sustainable practices.

Democracy and Agency

Another topic critical to the global discourse on ethics and the globalization of agriculture and food concerns the ability of each society to determine its position vis-à-vis the world at large. This is evident in relation to the land acquisitions that some states have pursued in less-developed countries so that they can export agricultural commodities and secure their own domestic food supplies. Critics of such projects have called them “land grabs,” arguing that many of these less-developed countries experience undernutrition and receive aid from the World Food Programme. Some researchers have accused countries of causing famines by engaging in such land acquisitions.

The concept of “food sovereignty” has emerged as a challenge to neoliberal policies to food and agriculture, phenomena such as “land grabs,” and notions of “food security” that emphasize decision making by state elites, advancements in agricultural production, and the role of large corporations (Carney 2011). “Food sovereignty” is said to be the right that peoples and countries have to food and to determining how they will produce or obtain food in ways that meet their nutritional, ecological, social, economic, and cultural needs. It is deemed a violation of food sovereignty when an international institution or a foreign government coerces a state to open its borders to imports of commodities and food products. Proponents of “food sovereignty” are concerned that the liberalization of trade threatens domestic agricultural sectors, the livelihood of farming households, human health, and the stability of rural areas. Another objection is that food imports may include products such as genetically modified crops that may be socially undesirable but may not be identified as such in labeling. Food sovereignty advocates also emphasize the inequality inherent in a system that enables developed countries to export agricultural products at much cheaper prices because of subsidies and price distortions. As a result, they believe that societies should be able to determine their own policies without pressure from international institutions, powerful state actors, or domestic governments pursuing individual or political agendas at

the expense of disadvantaged minorities. Critics find “food sovereignty,” however, to be open to interpretation, easily manipulable by elites, and difficult to gauge (Carney 2011).

Summary

Globalization is comprised of processes whereby people, things, ideas, and capital move across the globe. It does not have a definite starting point and its future mutations and consequences have yet to be determined. Contemporary ethical debates about the globalization of food largely relate to economic, cultural, health, and environmental concerns, as well those related to agency and democracy. As state and non-state actors as well as global civil society take measures to address the negative impacts of globalization and expand upon the benefits, new manifestations of globalization will emerge. Consumption has ethical implications, but the larger consequences of particular consumption patterns are not always clear. The global food system lacks transparency, traceability, and accountability, leaving consumers to make decisions based on the incomplete and sometimes distorted information available to them.

Introduction

Public concern about the consequences of “corporate” farms dates back to the early 1900s. While corporate farming has a technical or legal meaning about the form of business organization and ownership of farms, the term is usually used more broadly to refer to large-scale industrialized farms. Numerous studies raise the ethical issues about large-scale industrialized farms. One of the central concerns is the potential for these farms to have detrimental impacts on community life.

This entry provides an overview of the literature addressing the attributes and impacts of large-scale industrialized or “corporate” farms. It discusses the technical meaning versus popular usage of “corporate farms” and the manner by which scholarly research has conceptualized these farms. It also summarizes the many decades of research that has investigated the relationship between industrialized farming and public well-being. Extant research demonstrates a number of lines along which scholars have voiced concerns about industrialized farming. Finally, factors that might mitigate potential detrimental effects of industrialized farms are discussed.

Corporate Farms: Technical Definitions, Customary Conceptualizations, and Measures

Corporate farms are defined and studied in at least three ways, each one broadening upon the other. First, there are technical or legal definitions of these farms. As businesses, farms are classified by the form of business organization that the owners select on the basis of tax benefits and liability protection. Corporations are distinguished from typical small businesses organized as sole proprietorships, general partnerships, and other partnerships with various limited liability protections for owners. Goforth (2002) explains the legal differences between these different forms of organizing farms as businesses. Corporations are formed by filing articles of incorporation or corporate charters with state government. Farm corporations have built-in formalities such as

by-laws governing daily operations, relatively rigid management structures, and shareholders with voting rights that must approve organizational transactions such as dissolution and mergers. Shareholders do not have liability for losses of the corporation and are not entitled to report any loss on their personal taxes as a result of losses at the corporate level.

Various federal agencies collect data on corporate farms. The Agricultural Resource Management Survey conducted by the US Department of Agriculture shows that 3% of farms were incorporated in 2010, and they account for 21.6% of total US farm sales (McDonald 2012). But the vast majority of these corporate farms (2.6% of the total number of farms) are considered family owned with the majority of the shareholders being blood-related family members. Only 0.04% of US farms are nonfamily owned corporations. The proportion of nonfamily held incorporated farms has grown little over the past several decades (Lobao and Meyer 2001). The minuscule number of non-family relative to family corporations contrasts with the popular perception about corporate farming. It further suggests that ethical issues raised by legal incorporation per se are limited: most farms that are incorporated are done so to help families manage the operation and because of interests in estate planning, assurance of business continuity, limited liability, and potential tax advantages. The family criterion is important because it often forms some type of basis for corporate farm restrictions in different state laws.

A second conceptualization can be seen in the definitions used by states that have enacted corporate farming laws. These laws go beyond addressing whether or not a farm is an incorporated business. They are statutory or constitutional provisions limiting the power of corporations to engage in farming or agricultural production-related processes and to obtain land that is or could be used for agricultural production. Pittman (2004) provides a summary of these laws often called “anticorporate” farming laws. Varying by state, these laws involve criteria such as the number of and relationship among the shareholders, whether a family member “actually” conducts

farming operations, and whether shareholders reside or work on the farm. Nine Midwestern states have these laws in place. They often provide exemptions for nonprofit entities who own farms and for corporations who entered farming prior to the passage of any anticorporate farming act. These laws are established in the attempt to reduce the potential negative impacts of absentee-owned, large-scale farming on communities and the public at large and to protect family farmers from oligopolistic agribusiness.

The third conceptualization, the one most frequently assumed in the popular literature, is the use of the term corporate farms as synonymous with industrialized farms. As explained above, most “corporate farms” are in fact family owned and operated farms – hence, as a term, “corporate farming” is a misnomer. But the broader industrialization of farming has been of extensive concern to researchers due to the potential for detrimental effects on the public well-being. Hence, ethical issues raised by “corporate farms” should be subsumed under the more general question of the industrialization of farming.

The industrialization of farming refers to the transformation whereby farms have become larger scale, declined in number, and integrated more directly into production and marketing relationships with processors through vertical or contractual integration (Drabenstott and Smith 1996: p. 4). The industrialization of farming is often contrasted with the relative decline of traditional, moderate size family farming. Extensive research explains how farms have changed historically and the evolving patterns of farm size and structure (Buttel 2001; Lobao and Meyer 2001). Farming is often described as a dualistic system, composed of a few large farms with expanding market shares and many small farms that cannot sustain families. Over time, moderate size farms have been edged out of agriculture. Scale, measured in farm sales, is usually used as a measure of farm size. Very large farms (those with annual sales of over one-half million dollars per year) make up only 5% of all farms, but they account for more than half (53.7%) of total agricultural sales (Hoppe and Banker 2010: p. v). These very large farms have a median size of 1062 acres as compared to the

median for all US farms, 88 acres (Hoppe and Banker 2010: p. 8).

Accompanying the growth of scale of operations are organizational changes. These include an increase in the relative proportion of hired to family labor as well as greater use of incorporation as a form of legal organization, discussed above. Another organizational shift is the movement toward a more integrated industry from farm to grocery; this occurs through “contract production” and vertical integration that links farmers, food processors, seed companies, and other agribusiness (Barkema and Drabenstott 1996: p. 64). Vertical integration refers to operation of farms by firms that also operate in at least one other stage of the food chain, such as input supply, processing, and marketing. Examples of vertically integrated firms are large livestock producer/processor enterprises, such as Tyson. In addition to their direct involvement in farm production, agribusiness firms contract with farmers for goods and services. About 10% of farms operate under marketing or production contracts with agribusiness corporations (Hoppe and Banker 2010: p. 38). Marketing contracts are used by independent operators to reduce exposure to market price swings; these contracts stipulate a commodity price or pricing mechanism for delivered goods and are used mainly for crop and dairy commodities. Production contracts involve cost sharing arrangements and/or payment for operators’ services usually for hogs, poultry, and other livestock production except dairying. Production contracts extend agribusiness firms into direct farm production using the vehicle of the local farmer. In sum, agribusiness firms, depending on corporate strategy, may enter farming through direct operation of their own units and/or through employing local farmers to participate in production homework.

In classifying farms as “industrialized” or “family,” researchers distinguish between the construct (an ideal-type concept) and its actual measurement (variables used to define the concept in practice). When social scientists refer to “industrialized” farms, they invariably are referring to both scale and organizational characteristics of the farm unit. In general, but not always, scale coincides with organization. That is, large-scale farms

(relative to smaller or family farms) are more dependent on hired labor and managers and more likely to have absentee owners, to be incorporated, and to be vertically integrated with agribusiness. By contrast, family farming as an “ideal type” is usually conceptualized as an enterprise where the family unit owns a majority of property, makes managerial decisions, and provides the bulk of labor.

In terms of measurement, social scientists measure industrialized farming by both scale and organizational variables. Scale is usually measured by sales but sometimes by acreage and real estate and for livestock operations, animal inventory. The actual dollar value for scale indicators used by analysts to indicate a “large-scale” farm will obviously vary by the time period of study, by regional context, and by commodity. Organizational measures of industrialized farming include vertical integration of corporations into farming; production contract farming arrangements; absentee ownership of production factors; dependency on hired labor; operation by farm managers, as opposed to material operation by family members; and legal status as a corporation (family or nonfamily). But in practice, social scientists focus most on farm scale (sales) and use it as a general proxy measure to classify farms because it is simple, clear, and often correlated with organizational characteristics of units. In 2010, USDA categorized farms with over \$250,000 in annual sales as “large” farms and those with \$500,000 or more in annual sales as “very large” farms (Hoppe and Banker 2010).

Concerns About Public Well-Being

Numerous ethical concerns are raised about the potential for negative impacts on society due to the industrialization of farming, both globally and within the United States. The degree to which these concerns are warranted depends on the particular empirical case, including national and community context. Noted below are general issues that apply across nations and particularly developing nations. More detailed attention is then given to the US case.

Across Nations and the Developing World

Across nations, researchers have raised concerns about the industrialization of farming on public well-being. Farming systems globally are inherently uneven in their effects, conferring different costs and benefits across regions, communities, and social classes. Larger and fewer farms reduce the aggregate farm population within nations and alter farm and rural community class structure (Barrett et al. 2010). In contrast to assumptions that rural areas initially fall behind in well-being as farming becomes industrialized but later catch up to urban areas in income and employment over time, cumulative, uneven development may occur. That is, rural communities or regions may suffer long-term outmigration and persistent poverty, never fully recovering.

More broadly, some researchers see the industrialization of agriculture as symptomatic of broader and largely negative changes in the global food system. McMichael (2012) articulates this concern well. He explains how the power of capitalist elites, multinational corporations, and governments' acquiescence are leading to the development of a neoliberal food regime that unfolds across nations. The neoliberal food regime jeopardizes public well-being through escalating past trends toward multinational corporations' control of the global food supply. It raises profound questions within nations about agribusiness concentration, consumer health, food safety, and general sustainability of ecosystems. However, the most immediate effects of industrialized farms are on the day-to-day lives of people residing in the places where these farms are located. It is also at this level where social scientists have conducted a great deal of research over a long period of time.

For developing nations, the industrialization of farming has raised a series of specific concerns. A useful summary is provided by Schaeffer (1997). He denotes the following issues. Industrialization of agriculture creates a movement from subsistence farming to export agriculture. It may reduce domestic supply of staple food commodities. Periodic food shortages or even famine may occur as food prices rise. Farmers themselves become increasingly cash dependent and more

prone to debt crisis as they seek to maintain households and expand operations in order to compete. Rural class structure undergoes change. Smaller farmers may become displaced, and there may be a rise in landlessness. Overall, economic inequality among the rural population tends to grow. As large-scale farming expands, habitats may be destroyed, and general environmental degradation may occur. Gender inequality in farming also occurs. Perhaps the most detrimental effects have been in sub-Saharan Africa where women who were once direct food producers tend to be displaced disproportionately from this role as land is commodified and sold. Industrialized farms also tend to recruit gender-specific labor forces. Men usually have the first new opportunities for employment on these farms, while women may have reduced access to land and earning opportunities. In regions where household income is not pooled, such as much of sub-Saharan Africa, children and women may have health, nutritional, and other problems as mothers lack access to income to provide for their families.

The Case of the United States

Public concern about the industrialized farming in the United States began in the 1920s–1930s. Boles and Rupnow (1979: p. 471) note that during this period, concern centered on the potential negative effect of mechanization, foreclosure of farm land mortgages held by corporations, and corporate monopoly of land. Since that time, much of the concern has been directed to the impacts of industrialized farm on communities.

The classic study which gave rise to modern research concerned with the ethics of industrialized farming was conducted by Walter Goldschmidt, an anthropologist working with the US Department of Agriculture. In the late 1930s–early 1940s, he conducted a research project on the effects of industrialized farming using a matched pair of two California communities, Arvin, where large, absentee-owned, nonfamily operated farms were more numerous, and Dinuba, where locally owned, family operated farms were more numerous. The purpose of the study was to assess the consequences of a California law with a

provision placing acreage limitations on large farms located in California's Central Valley, so as to support family size farms in the region. Goldschmidt (1978: p. 458) notes that "Large landholders throughout the state and corporate interests generally opposed this provision while diverse church and other agrarian-oriented interests wanted this law applied to California. The comparative study of Arvin and Dinuba... was designed to determine the social consequences that might be anticipated for rural communities if the established law was applied or rescinded." Goldschmidt (1978) systematically documented the relationship between large-scale farming and its adverse consequences for a variety of community quality of life indicators. He found that, relative to the family farming community, Arvin's population had a small middle class and high proportion of hired workers. Family incomes were lower and poverty was higher. There were poorer quality schools and public services, fewer churches, civic organizations, and retail establishments. Arvin's residents also had less local control over public decisions, or "lack of democratic decision-making," as local government was prone to influence by outside agribusiness interests. By contrast, family farming Dinuba had a larger middle class, better socioeconomic conditions, high community stability, and civic participation. Goldschmidt's initial research report, made public in the early 1940s, angered large farmers. It was first silenced by USDA and then burned publicly in California along with John Steinbeck's *Grape of Wrath*. Not until 1978 was it made widely available to the public, published in book form.

As the structure of US agriculture has evolved toward larger and fewer farms, government and academic researchers have continued to investigate the extent to which large-scale, nonfamily owned and operated industrialized farms adversely affect communities. Congress has conducted inquiries, such as that by Senate Subcommittee on Monopoly dealing with Corporate Secrecy and Agribusiness, in which rural sociologists and agricultural economists provided testimony in 1973 about the dangers to communities posed by increasing corporate control of

agriculture (Boles and Rupnow 1979: pp. 468–469). The Office of Technology Assessment (OTA), concerned that the relative growth of large-scale industrialized farms might have adverse impacts on communities, commissioned a series of research papers on the topic. The OTA research came as a request from the Congress and was eventually published as a book by Swanson (1988). In the 1990s, public concern with industrialized farming began to be directed particularly on large integrated livestock producer/processor enterprises and to the issue of production contracts. Lobao and Stofferhan (2008) document four generations of work that have addressed the impacts of industrialized farming on communities, starting from Goldschmidt's qualitative work. This was followed by extensive quantitative research in the 1970s–1980s, revisionary work from the 1990s onward, and the most recent work focused on confined animal feeding operations (CAFOs).

The public concerns that industrialized farms raise are documented by Lobao and Stofferhan (2008) through a meta-analysis of 56 studies spanning over five decades of research. They classify the results of studies by the outcomes found, denoting three types of impacts. Socioeconomic well-being is most frequently studied: typical indicators are standard measures of economic performance such as employment growth, income levels and growth, and broader distributional conditions (poverty rates and income inequality). Community social fabric refers to social organizational features that reflect community stability and quality of social life. Indicators include population change, social disruption indicators (e.g., crime rates, births-to-teenagers, social-psychological stress, community conflict, and interference with enjoyment of property), educational attainments and schooling quality, health status, and civic participation (e.g., voluntary organizations and voting). Environmental indicators include quality of water, soil, and air, and health-related conditions.

Out of the total 56 studies analyzed, Lobao and Stofferhan (2008) concluded that largely detrimental impacts with regard to large-scale, industrialized farms were found in 82% (32) of the studies, some detrimental impacts were found in

14, and no evidence of detrimental impacts were found in 10. Such relative consistency continues to lead to the working hypothesis that industrialized farming jeopardizes well-being. Detrimental impacts are found across different measures of socioeconomic, social fabric, and environmental well-being and throughout regions of the country. Some examples of community quality of life that have been found to be adversely affected by industrialized farms are noted below:

Socioeconomic Well-Being (1) Lower relative incomes for certain segments of a community: greater income inequality (income polarization between affluent and poor) and greater poverty, (2) Higher unemployment rates, (3) Lower total community employment generated relative to family farms.

Social Fabric (1) Population: decline in local population size where family farms are replaced by industrialized farms and smaller population sustained by industrialized farms relative to family farms. (2) Class composition: rural social class structure becomes poorer (increases in hired labor). (3) Social disruption: increases in crime rates and civil suits and general increases in social conflict and increased stress or social-psychological problems among a community. (4) Civic participation: deterioration in community organizations and in less citizen involvement in social life. (5) Quality of local governance: less democratic political decision-making; public becomes less involved in local government as outside agribusiness increases its control over local decision-making. (6) Community services: fewer or poorer quality public services. (7) Retail trade: decreased retail trade and fewer, less diverse retail outlets. (8) Reduced enjoyment of property: deterioration of landscape and odor in communities with CAFOs. (9) Health problems: neighbors of CAFOs report upper respiratory, digestive tract disorder, and eye problems. (10) Real estate values: residences closest to CAFOs experience declining values relative to those more distant.

Environment (1). Ecosystem strains: depletion of water and other energy resources. (2). With regard

to CAFOs: safe-drinking law water violations, air quality problems, and increased risks of nutrient overload in soils.

In addition to the general issue of industrialized farms, specific concerns have been raised about production contracts, which as discussed above involve cost sharing or payments by agribusiness for operators' services such as in hogs and poultry production. First, production contracts are thought to alter agrarian social structure by creating a segment of farmers who are the structural equivalent of factory production homeworkers. Such contracts erode formally independent operators' autonomy in direct production, farm decision-making, and control over assets. Concern is also with the general well-being of contractees (operators) and their families given their asymmetrical relationship in bargaining power with agribusiness firms. There is an inherent structural imbalance in contract farming, and the degree to which this imbalance is manifest varies by specific contract arrangements. Ideally, production contracts are used to share risks and costs of production between contractee and contractor. But in practice, the bargaining power of external agribusiness is likely to result in a greater share of risks and costs of production borne by contractees and their families.

Public Policy and Other Factors to Promote Well-Being

Researchers have long questioned the degree to which public policy can be a mechanism for reducing the potential negative impacts of industrialized farming. For developing nations, researchers have often denoted the positive role appropriate agricultural policy can play in improving economic performance and alleviating rural poverty (Barrett et al. 2010). By contrast, in the United States, the limits and problems with farm programs are stressed. Analysts tend to see farm programs as contributing to the growth of industrialized farms (Winders 2009). While 61% of farmers receive no government payments (largely due to the commodities that are raised), for those that do, the largest farmers reap greater benefits, even though payments are capped

for the largest farms (Hoppe and Banker 2010: p. 33). Researchers charge farm programs with contributing to rising land values and reducing the risks of farming which over time promotes the growth of larger and fewer farms (Browne et al. 1992).

There is some evidence however that public policy in terms of state laws can help. Welsh (2009) reports states that regulating corporate involvement in farming with “anticorporate farming laws” tend to have more robust family farm sectors. Industrialized farming is less likely to have negative impacts in farm-dependent areas in these states. He notes also that state regulations that enhance the bargaining power of farmers with processors in terms of increasing prices and other aspects of agribusiness contracts also should improve the conditions of farmers and communities.

If the goal is to improve the lives of rural people overall, researchers note that nonfarm programs are far more effective than farm programs. Farm programs tend to subsidize property owners, as opposed to the mass of rural people (Brown et al. 1992). Further, farm households overall have higher median incomes than US nonfarm households (Hoppe and Banker 2010). Income transfers, food stamps, and other forms of federal intervention are beneficial to reducing poverty among needy rural people including farm labor.

Finally, researchers have identified general community attributes that may mitigate the potential for detrimental impact of industrialized farms. Stronger civic society, better quality non-farm industries and firms paying higher wages, and a political-institutional environment that supports the workforce in general such as through support for unionized labor, higher minimum wages, and adequate public assistance tend to raise the well-being of all workers in a community. These same factors are likely to buffer the potential effects of industrialized farms (Lobao 1990; Welsh 2009).

Summary

The term “corporate farm,” while popularly used, is better understood as the industrialization of

farming and growth of large-scale farms. In the United States, the vast majority of corporate farms are owned by families, and farm incorporation per se raises little in the way of inherent ethical issues. Rather, the industrialization of farming has been of concern to public well-being across the globe and has been studied in a vast scholarly literature. In a review of 56 studies, Lobao and Stofferhan (2008) found that in over 80% of these studies, the authors reached conclusions that industrialized farms had largely detrimental impacts. These studies reported three sets of detrimental outcomes on socioeconomic well-being, social fabric or stability of community life, and environmental problems. Such relative consistency in findings continues to lead to ethical concerns and the longstanding hypothesis derived from Walter Goldschmidt’s work that industrialized farming jeopardizes public well-being. Yet the degree to which such concerns are warranted is context dependent and varied over time and place. Government policy, the nonfarm economy, local civic society, and community institutions are contextual factors that appear to buffer potential impacts of industrialized farms while improving aggregate community well-being.

Corporate citizenship in the food industry; Corporate conscience in the alimentation sector; Responsible business dealing with food issues

Introduction

Corporate social responsibility (CSR) is connected with organizational accountability related to the social sphere of corporate performance. CSR policies in the food industry include different activities that aim at protecting various stakeholders and the environment related in some way to the alimentation sector. CSR is also known as corporate citizenship, corporate conscience, or sustainable or responsible business. It aims to balance the expectations of stakeholders with legal, social, and ethical obligations. CSR in the food industry often concerns such issues as food-borne diseases, food poisoning, nutrition, fair trade, different alimentation needs, as well as cultural differences in food production and consumption.

There are both internal and external dimensions to CSR. The internal sphere is viewed from the perspective of employees. The external one is viewed from the perspective of various

stakeholders. For example, the perception of individuals living near the food factories, mass media, suppliers, and customers is taken into account. CSR concerns various places, from factories to home kitchens.

There are several fields of interest in contemporary CSR in the food industry: (1) food quality, which includes such topics as nutritional composition, taste and visual aspects of food, certifications, and regional culture; (2) food sovereignty, which focuses on the right of local producers to manufacture regional food; (3) human welfare, which concentrates on conditions in the workplace; (4) animal welfare, which is connected with the proper handling of animals in food production; (5) ecological sustainability, which focuses on the usage of natural resources in producing food; and (6) transparency and traceability, which are connected with the opportunity to get acquainted with information on food production and various sources of food products (Deblonde et al. 2007).

The scope of CSR activities in various food-oriented business entities varies. Some of them stress all dimensions of their activities; they take care of employees, customers, natural environment, and society. As far as employees are concerned, companies from the alimentation sector highlight in their CSR policies that they are concerned about their workers, by offering them, e.g., medical packages, nutritional meals at work, and flexible working hours. As far as CSR for customers is concerned, companies aim at promoting healthy nutrition and lifestyle, paying attention to quality, and offering additional services for purchasers. Another popular sphere of interest for CSR-oriented companies is taking care of the natural environment. The companies operating in the food industry stress that they offer products in ecological packages or they use limited water resources in food production. As far as the societal dimension is concerned, companies underline that they help people in need, by, e.g., collecting food in their shops or spending some percentage of their income on charities.

Corporate social responsibility in the food industry is connected with the perception of risks (Bielenia-Grajewska 2013a). The increased role of communication media has enhanced our

awareness of food risks. Often people perceived risks as more dangerous than they really are. But often people perceive dangers as less risky than they are in reality. Thus, due to the optimistic bias, individuals may recognize risks in the wrong way or claim that some risks do not concern them (Miles et al. 1999).

In the case of potential situations related to risks, optimistic bias may concern, for example, the geographical area the food product stems, although nowadays food distribution is not restricted geographically. Another optimistic approach to food risks may be related to one's nutritional style or the age of already affected victims. Risks and CSR are also characterized by the potential juxtaposition of dangers, such as conflicting risks. For example, a factory may be the source of chemical risks in the neighborhood but, at the same time, it may be the only place of work for the local community (Heath 1994).

Methods in Analyzing CSR

There are various methodologies that can be used to analyze CSR in the food industry. Some scholars adapt qualitative and quantitative approaches, used in such disciplines as social studies and humanities, to observe how CSR is identified by various interested groups. Another option is to rely on discourse studies to show how messages are created to tailor the communication needs of various stakeholders and how these messages are understood by the target audience. Apart from the mentioned methods, some research groups work on special scientific methodologies for examining ethical issues in the food industry. They have created such tools as the ethical matrix, the ethical Delphi, the consensus conference, and the corporate moral responsibility kit that can be applied to study ethics in the alimentation sector (<http://www.ethicaltools.info>). For example, the ethical Delphi method focuses on the exchanges of expert opinions and arguments on ethical issues. A series of questionnaires are sent to geographically dispersed experts to facilitate collecting and clarifying knowledge on ethical notions (Millar et al. 2006).

CSR Communication

In the case of food risk communication, dangers should not only be highlighted but the way they can be effectively combated by the company should be discussed as well. It is not enough to notice that some problems appear and inform potential stakeholders about possible difficulties but additional information should be provided on how an organization plans to deal with such crises. In addition, feedback and suggested actions should be tailored to diversified stakeholders. One of the factors shaping CSR communication is the type of risk and its relevance for diversified interested groups. Customer concerns in relation to food-related jeopardies can be categorized as follows. The first group of dangers is the one that is important to all consumers and focuses on food security. The second set entails the notions of interest only to some groups of people, taking into account their lifestyle or nutritional preferences. The third group is connected with public opinion and how food products influence community and society (Brom 2000). Depending on the type of risk, the source of CSR-oriented information should be selected.

Sources of Information on CSR in the Food Industry

Effective communication on CSR issues should focus simultaneously on various aspects, on external and internal dimensions, and on online and offline spheres of interactions. As far as information on food safety is concerned, the following sources can be mentioned: food packages, magazine articles, TV cookery programs, leaflets, TV documentaries, other TV programs, recipes, family, radio programs, doctors and health personnel, friends, school, posters, university, fridge magnets, and tea towels (Redmond and Griffith 2005). The popularity of the mentioned sources differs, taking into account the reason for searching data and the types of users who want to gain information. For example, older individuals are more likely to opt for standard media (newspapers, television, radio) than for online

social networking tools in obtaining data on food issues. However, the selection of information source is often moment and context dependent.

As far as food crises are concerned, the dynamism of such situations makes online tools of communication more efficient since they are able to monitor the situation continuously. In addition, taking into account the mentioned sources on food issues, the process of knowledge transfer can be direct and indirect. For example, in the case of scientific articles, individuals read them to find relevant data. However, as far as television programs are concerned, learning on food aspects during programs related to other issues often takes place subconsciously.

With the growing role of the Internet in modern societies, the web constitutes an important tool of communicating CSR. There are various reasons why the online methods of communicating issues related to corporate social responsibility are gaining popularity. One of them is the relatively low cost of informing a potentially large group of stakeholders, regardless of their geographical location. Another hallmark is related with the possibility of changing content and inserting new information very quickly.

The last feature is especially important in the case of risk or crisis communication when a company has to react to extraordinary situations and inform stakeholders about its envisaged activities. However, it should be stated that this feature can serve the function of a two-edged sword in communication; online networks can work as efficient tools for disseminating information but, at the same time, they can become the source of data about the failures of companies in dealing with food crises and the platform for exchanging news among stakeholders. Thus, online networking tools should be an important element of communication with the target audience to ensure efficient and reliable information sources.

Modern times can be characterized by *information overload* since data provided in various sources is excessive (Misra and Stokols 2012). Thus, organizations have to select effective tools within texts and messages to attract stakeholders to the published pieces of information or news. In the magnitude of offered informational sources,

the written or spoken pieces of information must have features that make them outstanding among other informational sources.

Tools in Communicating CSR

There are various ways of informing stakeholders on CSR policies. One typology includes verbal and pictorial methods of communicating CSR. As far as the linguistic dimension of CSR is concerned, both literal and nonliteral methods of communication are used. Literal language encompasses all linguistic strategies that rely on their defined meaning; the selection of nouns, adjectives, and verbs is important in shaping CSR information. For example, the use of adjectives such as *careful*, *responsible*, and *reliable* shapes the positive attitude towards a company. The same applies to different verbs of action, such as *analyze*, *arrange*, *develop*, *improve*, or *participate*, that stress the active role of organizations in creating and sustaining responsible citizenship.

Nonliteral (figurative) tools of expression offer the unusual meaning of words and phrases. In the case of CSR communication in the food industry, figurative language offers novel perceptions and own interpretations of communicated issues. Since nonliteral linguistic instruments have the element of surprise, astonishment, or curiosity in them, they generally attract one's attention easier than standard forms of expression. Although there are different types of nonliteral tools, such as idioms, puns, similes, paradoxes, and metaphors, the last ones belong to the most popular vehicles of organizational communication.

CSR Through the Metaphorical Perspective

There are various reasons for the popularity of metaphors in the CSR discourse. First of all, the usage of metaphors in sustainable dialogue facilitates quick and effective communication since images and symbols understood by the wide

audience are used (e.g., Bielenia-Grajewska 2009). For example, some concepts from the domains of war, illness, or fairy tales are widely recognized by different stakeholders and offer immediate connotations. Secondly, in comparison with long and descriptive texts, metaphorical names are more efficient in terms of devoted time and used space. However, it should be noticed that symbolic language possesses some ambiguity in it and presents only selected aspects of some issues (Spicer and Alvesson 2011), and consequently, the responsibility is dislocated in communication. Some also claim that metaphors present meanings in a distorted mirror; they do not show the real situation and, consequently, the real danger connected with food risks is not described in detail.

Metaphors can be studied by taking into account the issue or the participants in the CSR discourse. The use of symbolic language in discussing food risks has the aim of exemplifying certain characteristics of them. For example, food-borne disease are pictured through war metaphors to show that food-borne illnesses are dangerous and, consequently, they require effective actions if one wants to defeat them. Their power is also stressed by comparing them to natural disasters that can be difficult to predict, spread quickly, and affect a considerably large number of people. The food itself can also be pictured through, e.g., the perspective of a journey metaphor to show that alimentation can become a vehicle for transporting diseases (Bielenia-Grajewska 2013b).

In addition to the topic approach in the discourse on CSR, corporate citizenship can be studied by looking at organizations from the perspective of metaphors. Thus, such concepts as *organization as a teacher* are popular in CSR discourse. This symbolic interpretation stresses the educational character of a company that is directed not only at gaining profit but also at educating stakeholders on how food should be prepared or stored. In addition, an organization can be pictured as a protector that takes care of safety (Bielenia-Grajewska 2014). These discursive strategies create the company identity in the eyes of the public by showing the attitude of companies to CSR through organizational metaphors.

Future of CSR Research

Another possibility of researching the CSR communication is by applying the neuroscientific research. One example is neuroethics that studies morality in CSR and how individuals react to morally arguable actions. The interest of neuroethics depends on the type of industries taken into account. For example, medicine, together with such aspects as the influence of medical substances on human beings, potentially involves more risks than other business activities that do not possess any direct involvement with health (Bielenia-Grajewska 2013c). Consequently, the food industry is also likely to attract the attention of specialists involved in neuroethics, taking into account the risks connected with, e.g., food poisoning and food-borne diseases. For example, neuroimaging techniques can be used to study participants' responses to food risk communication conducted by CSR-oriented companies. Such studies may help in selecting the best method to communicate food-related issues to potential stakeholders. These methods also offer the opportunity to study emotions and feelings concerning CSR that may not be disclosed by participants in the standard methods of questioning, such as questionnaires and interviews.

Summary

CSR in the food industry concerns different areas of investigation and concerns various stakeholders. Taking into account the growing competition in many sectors of the food industry and the accelerating role on social networking tools in exchanging information, organizations representing the alimentation sector should use diversified methods of communicating their attitude to the ethical, social, and legal sphere of organizational performance and establishing proper relations with the environment. Modern customers do not only take care of the quality and price of products offered on the market, but they become more and more aware of the sustainability of companies operating in the food industry. Thus, effective CSR policy is indispensable in the dialogue with diversified stakeholders.

Introduction

Cosmopolitanism is the thesis that there are certain universal values and transboundary or global responsibilities toward human beings anywhere. Localism is the thesis that local knowledge, local traditions, and local understandings of what is good for people are important to understanding and promoting well-being in any given locality. In respect to food and agriculture, typically a cosmopolitan is interested in questions like the following: since large numbers of people in the world are hungry or malnourished, what should be done to increase access to food, whether by aid, increased trade, or trade conducted under better rules; with new methods of agriculture; through reduction of food tariffs and other protectionist measures; and so on? Typically in respect to food and agriculture, the localist perspective will emphasize the importance of local knowledge and practical expertise and local experience of how to manage the land (agricultural techniques, what seeds work in what soils, etc.) and the importance of certain kinds of food that may have cultural, perhaps religious, meanings.

Do these two perspectives clash? The short answer is that they can but that they need not. If, for instance, a localist thinks that local values and conceptions are such that there cannot be a universal ethical perspective assumed by cosmopolitanism, then there is a clash. If, for instance, the cosmopolitan presents his/her view in such a way

that local perceptions of value are judged to be wrong because they conflict with the cosmopolitan account of universal values, then there is a clash. But if cosmopolitanism is presented in such a way that its universalism is sufficiently sensitive to the local values and knowledge that localism points to, and if localism is so understood as merely to stress the importance of the local for the full understanding of human well-being and what is needed to promote or maintain it, but accepts a global framework of responsibility for promoting and not undermining those conditions of well-being so understood, then there is no clash at all. Indeed, the two perspectives somewhat complement each other in response to a third approach – or cluster of approaches – that reflects the projections of interest and power within national politics, in geopolitics, and in the agendas of many multinational companies.

This entry explores the issues framed in the way above in more detail. While the author does not conceal his preference for the latter complementary approach, the entry's main function is to map the issues, so it also identifies where the sources of tension arise as well. In the first half, the entry looks at cosmopolitanism and localism in general, and in the second half, it applies this to some issues to do with food and agriculture.

Cosmopolitanism

Cosmopolitanism comes from the Greek root “cosmo-polites,” literally “citizen of the universe,” but it is usually understood to mean “world citizen” or “global citizen.” For the Stoics in the ancient world, it was a metaphysical affirmation that human identity was as members of the community of all human beings subject to the natural law or universal moral law, not merely based on their contingent identities as members of particular states, families, etc. What is retained in later periods, such as the European Enlightenment, and in the twentieth century is the claim that human beings belong to one moral community, that all human beings are equal in moral status, and that they have in principle obligations toward all fellow human beings, both not to harm them

and to some degree to help them (Brown and Kleingeld 2006).

This statement from Pogge, whose book *World Poverty and Human Rights* (2002) has become an important focus of cosmopolitan concern about world poverty, defines the position thus:

Three elements are shared by all cosmopolitan positions. First, individualism: the ultimate units of concern are human beings, or persons – rather than, say, family lines, tribes, ethnic, cultural or religious communities, nations, or states. . . . Second, universality: the status of ultimate unit of concern attaches to every living human being equally – not merely to some sub-set, such as men, aristocrats, Aryans, whites, or Muslims. Third, generality: this special status has global force. Persons are ultimate units of concern for everyone – not only for their compatriots, fellow religionists, or suchlike. (Pogge 2002, p. 169.

Thus, if one accepts the idea of being a global citizen, one may accept that one ought to support aid projects, that is, positively to help. One may buy fair trade food in order to reduce one's dependence on economic systems that may be "free trade" but are either less fair or unfair. One may join an organization like Amnesty International to reduce the injustice and hardship experienced by particular individuals in other parts of the world. One's engagement as a global citizen may express itself politically as a "globally oriented citizen" (Parekh 2005), for instance, through membership of civil society organizations campaigning to get one's government's foreign policy changed over trade agreements, climate change measures, debt relief, and so on.

Cosmopolitanism also has profound implications for how institutions and corporate bodies are assessed, whether these are nation-states, international organizations like the UN and its agencies, legal systems, or commercial organizations. If the ethical starting point is accepted that all human beings are equal in moral status, then at the very least an assessment can be made on how well or badly such institutions further or thwart human well-being anywhere. Thus, cosmopolitanism often offers a critique of nation-states and their foreign policies or what transnational corporations do. Given, for instance, that secure and sustainable access to sufficient healthy food and

clean water is among the fundamental goods that all human beings ought to have and have equally, do international trading policies help to realize this or help to do so as well as might be expected given political constraints, or not? If climate change is contributing to the reduction of such access for poor people, then does that fact add to the arguments for serious commitment from states to climate mitigation and assisting with adaptation?

There are two issues concerning cosmopolitanism that need to be identified, since how they are resolved will have a bearing on the relationship to localism.

First, insofar as cosmopolitanism is a commitment to the thesis that all human beings matter or that human well-being for any human being is of equal value, there is the question of how this well-being is defined, both in regard to (a) how it is validated, e.g., by cross-cultural dialogue, philosophical theorizing, or whatever, and (b) what its content is, whether its content is thin(ner), leaving much to individual and cultural interpretation, or thick(er) in terms of richer conceptions of what real well-being consists in (whatever people themselves might think) often linked to the acceptance of some (commonly religious) worldview (Dower 2007). The danger with the former is that it may lead to allowing too wide a range of conceptions of well-being as being acceptable. The danger with the latter is that it leads to the projection or imposition of ideas derived from one culture or tradition, onto the rest of the world, thus constituting a form of cultural imperialism. But there is also a practical danger in the latter here, in that those with cosmopolitan ideals who are in positions of power or influence in respect to devising appropriate global policies, e.g., on food or agriculture, may, without wishing to so, make proposals that reflect universalist assumptions of a "one cap fits all" kind that are not sufficiently sensitive to what is needed in different circumstances. This is where in practice, whatever theoretical accommodation can be made, tensions between localism and cosmopolitanism can arise.

The issue of what kind of cosmopolitan conception of well-being is appropriate may not merely arise because cosmopolitans may put a

very strong specific a conception of well-being into the picture; it can arise because those in power in national and international organizations come with a conception of human well-being which is actually very thin. The main example of this is the perspective of the libertarian, particularly the economic libertarian, whose conception of the central value of human well-being as being the exercise of liberty in a minimally fettered free market (Nozick 1974) leads to a disregard for the diverse nonmarket-driven values that localism often favors. The kind of cosmopolitanism that is consistent with localism is quite different from this, but it is worth noting that although free market advocates do not often present themselves as cosmopolitans, they are nevertheless cosmopolitans insofar as they have a core value – liberty – which they think is the key to well-being everywhere and ought to be promoted everywhere.

The second issue concerns the nature and extent of cosmopolitan transboundary obligation. Cosmopolitanism can be presented in a strong form and as such can be in conflict with both localism and other theories that prioritize obligations to limited groups, but it can be presented in a less strong form and as such need not be in conflict with localism.

Two elements combine to create the really strong thesis; first, that if all human beings matter equally, then in moral decision making when people act for the good of others, they should not privilege the good of some human beings over that of others just because they belong to their country, their locality or community, or for that matter their family, or if they do (as people actually do!), there has to be some special justification for so doing. Second, they always ought to act so as to promote human well-being anywhere as much as possible. If these two claims are combined, a strong ethical demand is entailed that, for those who live in richer countries, since the suffering of so many people elsewhere in the world is so much greater than that in one's own country, one ought really to devote most of one's money and time to addressing these distant ills.

One version of this offered by Peter Singer in his article "Famine, Affluence, and Morality"

(Singer 1972) is well known. He argues that just as a lecturer would at some cost to himself rescue a drowning child in a lake, acting on the principle "if it is in our power to prevent something very bad from happening without thereby sacrificing anything of comparable moral importance, we ought to do it," so are those in richer countries ought to prevent deaths in poorer countries as much as they can. Countless articles are devoted to replying to its challenges. A similar kind of ethical challenge has become more prominent in recent years concerning individual's responses to climate change. Should one do all one can to reduce one's direct and indirect carbon footprint, with all that that entails for not just how (much) one travels, but what one eats (e.g., where food comes from, eat less or no meat, and so on)?

A weaker form of cosmopolitanism does not have these implications: it is the claim that one has significant but not overwhelming obligations to promote good anywhere and reduce one's contribution to harms anywhere and that while the privileging of the promotion of the good of some humans (especially family, friends, and oneself) can be justified, there are distinct limits to what is reasonable in this regard. Where the lines are drawn and how they are justified is a complex matter. What is important is the cosmopolitan perspective, which, if it were adopted by significantly large numbers of people, would lead to significant changes in public policy.

Localism

Localism refers to a range of approaches that prioritize the local (O'Riordan 2001; McIntosh 2001). The three main areas of prioritization may be seen as practical, cultural, and political. Localism may put emphasis on the need for greater production of goods – whether of food, furniture, arts and crafts, clothes, or whatever – combined with greater consumption of these goods by people in the same locality. The reasons for this may be environmental, for instance, in reducing food miles or goods miles or in reconnecting to the landscape (Cooper 1992); or they may be economic in that more economic functioning locally

with less dependence on wider networks is good for people living in the locality because there is greater control (including the use of local currencies as in LETS) but also because it contributes to a stronger sense of community. Sometimes the production of goods locally is linked to a desire to preserve or reactivate traditional skills and crafts that are in danger of being lost. Particularly in poorer countries, the localist outlook may be expressed in a rejection of development models that are seen as coming from outside and the affirmation of local knowledge.

A communitarian basis for localism may sometimes be emphasized more generally – that people's identities are importantly grounded in the shared history and customs of a given locality. Furthermore, localism may stress the importance of local governance and government with significant degrees of autonomy from larger political systems. Thus, in this respect, generally localism is contrasted with the idea of political control at a regional or nation-state level (though interestingly enough what is called bioregionalism is inspired by a form of localism).

More generally localism, at least in its modern formations often called *relocalism*, is a kind of reaction to the trends of globalization, insofar as globalization represents the pervasive impact of global economic forces on what happens locally in almost all parts of the world and also represents the penetration of global culture into the local, thus tending toward the homogenization of cultures (Scholte 2000). This response to the trends of globalization has led some writers to describe or advocate a process known as *glocalization*, in which the forces of globalization are counterbalanced by (re)localizing tendencies (Robertson 1992). But there may lie behind these localist ideas a deeper thesis, namely, that in emphasizing the local, one's prioritizing it either denies or downgrades the importance of what lies outside the local.

This kind of perspective is often identified as a form of communitarianism which may emphasize two things (Bell 2012). First, the values that are accepted in the locality are at least partly and significantly derived from that local community's shared history and traditions and get their

validation from that fact, and as such, insofar as it is also claimed that values vary from one community to another, some thesis of relativism is accepted and therefore some skepticism toward the whole global ethics perspective (this is even more prominent in a view called *ethical particularism* which opposes the ethical generalism underlying cosmopolitanism (Dancy 2001)). Second, because of the reciprocal ties arising from people living together, the scope of people's obligations are first and foremost to members of their local community (or one's country as a political community), much less toward the world as a whole since it is not a community in the relevant sense. If people in a given local community (or for that matter the wider community of their state) feel some obligations toward people in some other parts of the world, then this is an accident of the fact that some concerns have developed through their history, not a consequence of some cosmopolitan global ethics.

The Relationship Between Cosmopolitanism and Localism

It will be apparent from the account of cosmopolitanism and localism given that they can be consistent with each other but that they need not be. The reason for this needs to be spelled out.

If cosmopolitanism is presented in a strong form that asserts that a general and complete account of human well-being can be applied to any situation anywhere (so that local understandings, if different, are wrong), then it conflicts with localism in any form. If cosmopolitanism is the claim that all obligations have to be justified as consistent with or in some way contributory toward the promotion of well-being of humans anywhere, it conflicts with localism in any form that asserts locally based obligations. Conversely, if localism is asserted in a strong form (less likely) that all values are locally sourced and validated, it conflicts with any cosmopolitanism that asserts a universal account of value. If again localism claims that obligations are primarily with fellow localists, it conflicts with any cosmopolitanism that asserts significant transboundary obligations.

There is of course left the third, arguably more common, alternative. Cosmopolitanism is asserted in some form to the effect that whatever universal values there are, they are to be so understood that they are contextually sensitive and open to many local interpretations (Pogge 2002); and indeed, it welcomes in general the maintenance of or return to what localists favored – local sourcing of food and other goods, a strong sense of local community, robust local governance, and so on – as furthering human well-being. Cosmopolitanism also asserts that however much new scientific and technical developments are promoted, that is done in such a way that allows for the input of local wisdom and knowledge, and that global obligations are not so strong as to undermine the range of rights and obligations people have in local communities. Localism is asserted in such a way that while it resists pressures from outside toward uniformity or unduly economic or consumerist models of well-being that may come from the state or wider processes of globalization or resists excessive loyalty to wider entities such as the state, it does acknowledge a common global value framework and the idea of transboundary or global responsibility in principle and indeed welcomes it, particularly if that cosmopolitan perspective actually supported local communities that resist pressures from other sources such as central governments and big business.

The entry now turns to some issues concerning food and agriculture to illustrate further the above framework (Blatz 1991).

Access to Food

Whatever else cosmopolitans insist on, they insist on claiming that all human beings should have access to the conditions of a reasonable life or a life one has reason to want to lead (Sen 1999) and that this includes minimum access to such things as adequate healthy food, enough potable water, proper shelter and clothing, security against attack on one's person or property, education into relevant life skills, medical care, participation in communal decision making, etc. (Pogge 2002). The aspect nowadays that is made explicit (what was

implicit before) is that access to those things is sustainable. If a cosmopolitan uses the language of rights – which he/she need not – he/she will talk of the human right to food, water, etc.

Almost everyone would subscribe to such claims or at least to the ideal of a world in which these things were realized. Why then do over a billion of the world's population remain in absolute poverty with so little access to food that they are starving or malnourished? It is generally recognized that currently the problem is not that there is not enough food in the world – and indeed, many would argue that with improved methods of agriculture or switching to much more nonmeat-based diets (since feeding grain to animals is a very inefficient way of producing protein), even more food could be produced.

However, one dimension of the planet's finiteness is its finite capacity to produce on a renewable basis food for humans, and at some point, increasing human populations will bump up against these limits; and indeed, this capacity may be being reduced through land degradation. The other two dimensions of finiteness are the planet's finite capacity to provide nonrenewable resources and its finite capacity to absorb the effects of human activities without deleterious effect, as can be seen with species loss, pollution, and CO₂ emissions. But the three dimensions are all interlinked in practical terms to the challenge of devising appropriate strategies for “feeding the world” and so on. In some ways, especially in light of the likely effects of climate change, this aspect – the global capacity to produce enough food – is beginning to play a role in global thinking about food under the banner of “food security,” an agenda which is as much driven by concerns of wealthy countries about their continued access to the foods they want as by concerns for access to food for the very poor. Food insecurity has been the lot of the very poor on a large scale for decades.

The reason currently however for lack of access to enough food for the poor is not one of absolute scarcity but one of distribution, in which very poor people do not have access to sufficient food either because they do not have enough fertile land to grow it or because they do not get

it from others through either having enough resources to acquire it in economic transactions or happening to be the recipients of food through aid programs. Since these are not natural facts (such as acute shortages caused by natural disasters) but facts for which the causes lie in human *decisions* which could be different, it is from the point of view of many cosmopolitans an issue of justice, including global justice (Pogge 2001), since the actors involved include actors elsewhere. These are nation-states, business companies, citizens, and consumers in other parts of the world, all of whom could act differently.

It is one thing to say that people all have a right to food (or, e.g., water), and another to say that this right to food (or water) has a priority over other rights because it concerns the basic minimum conditions of life. Consider property and land rights within any country including poor countries. How far do they impede fair distribution? Should there be a radical land reform? Consider intellectual property rights such as those enshrined in TRIPS (Trade-Related Aspects of Intellectual Property Rights) agreements, which now form a major part of the WTO (World Trade Organization) agenda in which large companies are able to exert such powerful influence in determining the price of seeds that poor farmers have to pay. Consider the perspective of countries pursuing their economic interests individually or collectively, as in the case of EU's (European Union's) CAP (Common Agricultural Policy), with protectionist measures. This is commonly seen as asserting their rights to national self-interest behind which is the right of their citizens to enjoy a much higher standard of living than that experienced by the very poor. Are these acceptable, given the effects on the very poor?

Controversies exist over whether such regimes with their embedded rights contribute to extreme poverty and the poor's access to sufficient food and, if so, whether they are justified if they have these effects. On the whole, most modern cosmopolitans – other than those who are libertarians in their approach or think that in the long run such regimes tend to the general good (as an aspect of what is sometimes called “trickle down” development) – question to varying degrees such

regimes and see their claimed justifications stem mainly from alternative paradigms of international relations or business ethics.

Be that as it may, whatever the arguments are in what is sometimes called the “politics of food” (Tansey and Rajotte 2008) – for and against political and institutional changes as a significant contributory factor in enabling poor people to be less poor and to have more food, it is commonly assumed, both by those who see it in cosmopolitan terms and those who do not, that a major contribution to reducing food shortages for poor people themselves is practical change, for instance in agricultural methods.

Aid programs – whether national bilateral or multilateral or government based or NGO based (nongovernmental organization based) – of course play their role, not merely in emergency or humanitarian situations but in providing development assistance. The difference between emergency aid and development assistance can be illustrated by a quotation from De Schutter, “Save in situations of natural disasters or civil strife, the right to food is not the right to be fed; it is the right to feed oneself in dignity” (De Schutter 2009, p. 8). The aim of the latter is (or ought to be) to empower poor people either to produce more food themselves or to acquire more wealth so that they can buy more food. Such aid programs will often involve the provision of agricultural equipment, providing better access to water – a critical factor not just for drinking water but agriculture itself – or the introduction of new agricultural techniques.

This now leads to localism. Localists living in poorer countries may protest at a lot of what is done or alternatively not done as contributing to their not having enough access to food. Poor people may feel that their opportunities to grow food are thwarted by larger economic forces over which they have no control – property investors from the cities, large-scale operations of transnational companies, the development of monoculture regimes producing cash crops driven by export markets, seeds they have to buy at high prices, and so on. The Green Revolutions have been seen as having their downsides – for instance, the very poor not being able to afford

the fertilizers or pesticides that are needed to get the extra benefits of the high-yield crops. In other words, they may protest at the lack of control they have in their communities.

In respect to the aid given by donors, again there may be concerns that not sufficient attention is paid to local knowledge about farming techniques or about local seeds (which may be well adapted to local terrains, etc.). The outside expert may not recognize that sometimes the poor are not disempowered by their lack of appropriate agricultural knowledge but by other factors. Much of the attraction to the approach of E.F. Schumacher's *Small Is Beautiful* (Schumacher 1973), later continued in the work of Practical Action, which he founded under the name the Intermediate Technology Development Group, was the recognition that high-tech solutions were not right for many local conditions.

It should be apparent that these concerns of a localist kind are not as such opposed to cosmopolitan concerns about "feeding the world." Rather what they are up against are tendencies that stem from other ways of thinking connected with inter alia: the rights of nation-states to pursue their national interests even at the expense of what would be better from a global point of view, the rights embedded in economic regimes within countries that trump the rights of the poor, and the rights of companies to maximize profits. Of course some cosmopolitans might have some sympathy for these rights, but generally nowadays cosmopolitans are as concerned as localists about these factors.

The Environment

There are many environmental issues that have an impact on food and agriculture, but the focus here is on two issues – climate change and water. Clearly climate change is likely to affect, if it is not already affecting, the capacity to grow food in particular places and areas, because, for instance, of reduced rainfall, and much of this change is occurring or will occur in parts of the world where poor people live. So whatever general arguments there are for mitigating emissions to reduce the collective impact on human well-being in the

future, there are good reasons both to mitigate the particular impacts on the world's poor now and also to help with adaptation (Garvey 2008). Here, there is largely convergence between the cosmopolitan who says that one has serious reasons to reduce one's emissions in various ways for the good of all in the world and the localist who, other things being equal, wants his/her environment to remain a "field of significance" he/she positively values (Cooper 1992).

A more complex relationship emerges in the case of food miles. If there are significant carbon costs from long-haul transportation, then one way of discharging one's environmental responsibility to reduce emissions is to reduce dependency on such foods. There are two other kinds of reason; first, as noted before, localists may argue for this since locally sourced food contributes to local economy, identity, and community; second, as a measure in a country's food security policy, it makes it less dependent on imports from other parts of the world.

However, if such preferences for local food and less reliance on imports from distant countries were to become widespread, it would have major implications for what happens in the countries where these foods are produced, which might not always be well received by local communities there. Thus, certain measures may not be to the advantage of all localities. Localism is not an approach that produces a preestablished harmony of interests, and a cosmopolitan's wider perspective may be needed to help lessen conflicts of interest where they arise. For example, the fair trade movement is not premised on reducing food imports but making them more consistent with the principles of global justice, so what's good for one community – more locally sourced food – might not be good for another, namely, less food wanted that is fairly traded. In this case, a resolution might be a reduction only of goods traded otherwise, that is, goods that come from business corporations in poorer countries that are not pro-poor and indeed may take up land in competition with what people want in local communities in poorer countries.

An interesting aspect of this relates to the issue of water. Access to water is a critical issue for the

future of agriculture since agriculture depends heavily on the amount of water available in given areas. It is well recognized that one of the sources of conflict in the future will be competition between countries for water, particularly water that runs in rivers through several territories. But at another level, from an ethical point of view, the most critical issue has to do with what is needed so that all people have secure and sustainable access to sufficient potable water and sufficient water for the production of crops that they need, etc. The right to water as the right to sufficient potable water for health and for adequate economic livelihood needs to be contrasted with and prioritized over any claimed right to water as a right that one has to any amount of water one wants (and can pay for) to satisfy one's desires for affluent living and to maintain the industries that produce the goods associated with affluent living. It is not that it is wrong to want these things as such, but an entitlement to the water necessary to these things is not of the same moral order as the basic right to water. At least this is what a cosmopolitan who was not a libertarian would claim.

This is not just a theoretical point. Increasingly it is recognized that what happens in one part of the world has an impact on other parts of the world even in regard to water. The amount of water one actually uses needs to be distinguished from the amount of water "embedded" in the goods that one uses (called "embedded" or "virtual" water). Consider a cup of tea with milk and sugar: maybe there is 1/3 l here. But consider the water used to grow the tea and sugar and to rear the cow, estimated to be over 30 l (BBC 2010). This is a rather dramatic example of what is called one's indirect environmental footprint. Its relevance to what happens in other parts of the world is this: if large amounts of water are used elsewhere to produce things that people want – not just food but the whole range of goods and components for goods – what impact does that usage have on the distribution of access to water in the other parts of the world where the goods come from? Sugar and tea plantations may not necessarily be the best use of agricultural land or the water needed for them from the point of view of what would be best for the

very poor who may have very limited access to water needed for life and livelihood.

Another example sometimes given that illustrates these issues and others raised in this entry is that of cut flowers flown from developing countries. Whether the development of this kind of use of agricultural land is to be welcomed raises big issues. It is something that can be questioned for all sorts of reasons, not just over the use of water of course, from both cosmopolitan and localist perspectives. Should land be used for "luxuries" for distant people where people are starving? What about the environmental costs of air transportation? Does not however the very raising of these questions strike at the heart not only of the international free market but also of the rights of entrepreneurs to use land to grow whatever they want – whether it is flowers, tobacco, or foods – for which they see that there are markets, local, national, or international? Arguably these questions do not do this. Rather they provide a reminder that there are many considerations other than the exercise of economic liberty that ought to influence the decisions people make, whether as individuals or as members of commercial or political institutions, locally, nationally, or globally.

Conclusion

Cosmopolitanism and localism offer very different perspectives on what is ethically important. In examining issues to do with food and agriculture, it can be seen that sometimes they are in tension with each other. But more generally there are convergences of ethical concern in the face of economic and political pressures from other sources.

Summary

Cosmopolitanism asserts that there is a universal value framework which includes significant transboundary obligations. Localism asserts the importance of local values and knowledge. They can conflict if cosmopolitanism questions the importance of local values and knowledge or localism questions significant transboundary obligations.

But they can be combined as the thesis of global responsibility to promote the conditions of human well-being partly defined in localist terms. Often they provide a common approach opposed to trends derived from national politics, geopolitics, and the global economy. In the second half of the entry, these approaches and their relationship are further illustrated with discussion of issues to do with food and agriculture, especially access to food, climate change, and water.

Introduction

Issues regarding the ethics, politics, security, and sovereignty of food and agriculture remain a relatively peripheral focus in criminology. However, a growing body of scholarship has been developing within criminology which focuses on food and agricultural issues and their links to criminality, deviance, and harm. Reece Walters provides valuable contributions to this area on the topic of genetically modified (GM) food; his book *Eco Crime and Genetically Modified Food* (2010)

and his numerous publications offer important connections between GM food and issues like political corruption, corporate monopolies, and environmental harm. Several other important contributions to this area of criminology are included here, such as Hazel Croall's (2013) chapter "Food crime" and Goyes and South's (2016) article "Land-Grabs, Biopiracy and the Inversion of Justice in Colombia." In this entry, criminological analyses of food and agriculture are detailed within the context of ethics – that is to say, the morality of criminal and deviant behaviors are a central aspect of this discussion.

Various ethical issues regarding the production and consumption of food such as hunting, vegetarianism, abattoirs, industrial agriculture, and GM foods and crops can be analyzed through a criminological lens. The incorporation of food and agricultural ethics into the discipline of criminology can be usefully separated into two broad (and overlapping) categories: *traditional criminology* and *green criminology*. Traditional criminology covers issues regarding behaviors/actions that are defined as illegal; these include areas such as the cultivation of illicit drugs and the negligent production of hazardous foods. Green criminology, which is a perspective and subdiscipline within criminology, highlights forms of environmental harm not included in legal definitions as well as the criminalization of environmentally beneficial (or benign) activities. This category involves exploring the notion of harm (environmental, social, etc.) and exposes a range of issues not necessarily categorized as criminal. These two categories are each discussed in turn.

Crimes Concerning Food and Agriculture

Criminal behavior, corporate negligence and liability, and notions of victimhood are among the more "traditional" categories of criminology from which food and agricultural ethics can be studied. The term traditional is not used here to critique or delimit the discipline of criminology; it is needed for situating the types of criminological inquiry commonly associated with the discipline and to help identify new inquiries beyond these types. It

is also important to note that traditional examples of criminological inquiry regarding food and agriculture are often intertwined with more nuanced discussions of harm. This section reviews three examples that effectively illustrate the study of crime in the context of food and agriculture: international law, illicit drug crops, and “food crimes.”

International Law

Walters (2004, 2006) discusses the role international laws, and treaties have begun to play as hunger-stricken countries have begun to reject GM food aid from the USA over concerns of potentially negative impacts to human health and biodiversity and as the USA is being accused of using food aid programs as a strategy to subsidize US farmers. Walters’ (2006) article “Crime, bio-agriculture and the exploitation of hunger” details the development of international environmental laws, such as the *Cartagena Protocol* and the *International Treaty on Plant Genetic Resource for Food and Agriculture*, which implement provisions to make it “illegal to distribute and trade in GM food products without the express written consent of the receiving government” (p. 39). Also, the introduction of such international environmental laws provides nations, such as Zambia, with a better capacity to develop their own legislative frameworks and resist the influences of powerful corporations and governments (Walters 2006).

Goyes and South (2016) explore aspects of international law regarding biotechnology and the use of genetic resources. This article applies a criminological perspective to the process of bioprospecting, or *biopiracy* – which is the appropriation of nature in the form of knowledge, knowledge which becomes intellectual property through international trade and property law (Goyes and South 2016). Although focused on laws and experiences in Columbia, Goyes and South (2016) also look at the associated impacts of international trade agreements and treaties like the World Trade Organization’s international agreement on *Trade-Related Aspects of Intellectual Property Rights* (TRIPS) and the 1991 *International Convention for the Protection of New Varieties of Plants* (UPOV 91) which protect the

patenting and commercialization of genetic materials derived from wild plant relatives. These agreements (as well as associated national laws) are implemented to protect the discoveries of biotechnology through international patent laws, but become linked to social and ecological harms when considered in a wider context. For Goyes and South (2016), the harms resulting from biopiracy represents what they term an *inversion of justice*, wherein traditional forms of knowledge are taken from its original “owners,” given patents and other protections, while effectively diminishing the “dignity, self-determination and independence” of these original owners (p. 6). Walters (2006) and Goyes and South (2016) effectively showcase the development of international (as well as national and regional) laws and their impact on the construction of legality and ethics regarding issues like plant genetics as intellectual property.

Illicit Drug Cultivation

Rosa del Olmo (1998) outlines the ecological impact of illicit drug cultivation from two distinct angles, the production of illicit drugs and the destruction of illicit drug crops. She provides a comprehensive lens for exploring the ecological links to drug crops by looking at both the chemical wastes created from this illicit industry and the damaging herbicides used by drug crop eradication efforts (particularly the efforts of the USA).

Significant ecological impacts occur as a direct result of the cultivation of illicit drug crops and the subsequent production activities; coca cultivation and cocaine production in South America provide a fitting example. Here, the Peruvian and Columbian Amazonia have declined by hundreds of thousands of hectares due to coca production practices, such as slash-and-burn techniques and the unregulated use of chemical fertilizers (del Olmo 1998).

The eradication of illicit drug crops can also cause negative impacts to the environment. A common means for drug crop destruction/eradication is the use of aerial fumigation with herbicides, including paraquat (or Gramoxone), 2,4-D, and glyphosate (or “RoundUp”). Del Olmo (1998) explains that the efforts of the US

Government are a large force behind the eradication programs initiated to control the availability of illicit drugs in Central and South America. Rolled out in Mexico and Columbia, these programs have led to significant debates over the potential health and environmental impacts of the herbicides used in aerial fumigation. Opposition in Columbia led to months of protests in 1996, which involved deadly confrontations between armed forces and over 50,000 peasants (del Olmo 1998).

Another critical factor in this scenario are the peasants who raise these crops as their only means of income; poverty, isolation, and a lack of opportunities play a key role in the prevalence of illicit drug production. Interestingly, since the introduction of eradication programs, illicit drug production has significantly increased rather than diminished. Del Olmo's (1998) analysis provides important insight into the complexity of criminality and harm in the context of illicit drug cultivation.

"Food Crimes"

Cheng (2012), Croall (2013), and Walters (2007) all identify "food crime" as an object of criminological inquiry. Food crime has been defined as "a wide variety of activities that are inconsistent with or violate any criminal law, civil law, administrative law, rule, ruling, regulation or norm expected of members of the food industry" (Cheng 2012, p. 257). The concept of food crime allows several interrelated aspects of the food industry to be explored within the contexts of criminality and deviance.

Croall (2013) explores the different forms of crime related to the food chain and details the criminological significance of food crime. Croall's chapter covers a variety of contexts of food crime, including production, distribution, food preparation, and the selling and marketing of food. Looking at food production, one interesting example is "black fishing." This is the criminal act of catching undeclared (over quota) fish and involves the coordination of fishers, processors, and haulers. Black fishing is so extensive that some estimates suggest it may be equal to legally caught quantities (Croall 2013). In the

context of food manufacturing and distribution, there are features such as food additives, sell-by dates, and modern processes like mechanically recovered meat (which involves the use of animal parts not typically consumed) which create a complex environment susceptible to fraud and deception. There are a variety of food crime examples within manufacturing – one being Tesco's (a British supermarket chain) failure to declare added water, glucose, syrup, and salt on the labels of their pork legs (Croall 2013). Two other examples of food crimes reviewed by criminologists include "Starlink" (the genetically modified corn) and the 2007 pet food recall. In 2000, Starlink corn, which was prohibited for human consumption, was identified in supermarket taco shells by Friends of the Earth (Walters 2010). In 2007, a pet food recall was initiated by Menu Foods who recalled over 150 different brands of tainted pet food (Fitzgerald 2010). Based on estimates, this recall led to hundreds, if not thousands, of animal deaths (Fitzgerald 2010).

In some cases of food crime, chemicals are even added to foods to make consumers hungrier to increase purchases (Cheng 2012). And melamine (a chemical used in plastics) has been added to powdered infant formula in China to boost protein content – this led to the hospitalization of tens of thousands of children. Crimes in the context of food distribution can also involve the intentional sale of food not fit for human consumption (destined only for pet food production) to hospitals, schools, and supermarkets – this process is sometimes referred to as "food laundering" (Croall 2013).

Cheng (2012) suggests the prevalence of food crime occurs in the context of "cheap capitalism" "characterized by low prices, inferior quality and unsafe condition of goods or services to maximize profits" (p. 254). Furthermore, Walters' (2007) article "Food crime, regulation and the biotech harvest" looks at GM food in the context of state, corporate, and transnational crimes. Walters (2007) suggests a "global criminology" is necessary for grappling with the complex international events regarding the production of, and trade in, GM foods. He also provides an important discussion of "eco-crimes," engaging with the

differences between environmental harms in the context of legal frameworks and criminal sanctions, and acts of environmental harm not covered by legal statutes. For Croall (2013), “Wherever ‘food crime’ fits within criminology, and whether or not it should become a ‘new’ criminological category, its analysis inevitably involves placing it in the context of the wider features of food production, some of which can be seen as ‘criminogenic’” (p. 224).

Harms Concerning Food and Agriculture

As illustrated, much of the criminological research on food and agriculture engages, at least to some degree, with the boundaries of criminological scholarship (particularly regarding the environment). This engagement with criminological boundaries is often identified within the perspective of green criminology, a growing body of scholarship developed for incorporating socio-ecological issues into the agenda of criminology. For instance, Walters (2004) looks at the “legal, ethical, economic, medical and environmental concerns about GM foods” (p. 151), and Halsey (1997) and Tourangeau (2015) use industrial hemp to critique rigid conceptions of ecological harm. Literature dealing with the connections between food and agriculture and instances of social and environmental harm provide an important extension of the criminological lens, incorporating issues beyond discussions of legality. This section is divided into two means by which criminological inquiries regarding food and agriculture are extended beyond legal definitions: (1) socially and ecologically harmful activities which operate beyond the scope of legal/criminal investigations and (2) socially and ecologically beneficial activities which are framed as harmful or deviant and face circumstances of criminalization, regulation, and deterrence.

Legal and Under-Regulated Harms Regarding Food and Agriculture

Research in criminology, namely, within the sub-discipline of green criminology, has begun to view legal and under-regulated social and

environmental harms through a criminological lens. With regard to food and agricultural ethics, Reece Walters and Hanneke Mol each provide fitting examples.

Walters (2004, 2006, 2010) examines the GM food industry from a criminological perspective. He examines the “legal and ethical dilemmas that surround this new food source and examines the controversies that surround its production” (Walters 2010, p. 6). While Walters’ work certainly encompasses an exploration of criminality within the agri-biotech industry – for instance, the illegal sale of GM Starlink corn in supermarkets – the focus is largely on the extension of criminological boundaries to include the legal and unregulated harms of GM technologies, such as the creation of super weeds, allergenic reactions, and the degradation of ecosystems. A key element in this discussion of harm and GM foods/crops is political and economic power. According to Walters (2010)

the corporate power and influence of biotech companies cannot be over emphasised. The ability to produce sympathetic and supportive ‘science’, to lobby politicians, to sue farmers, to exploit developing countries and undermine conventional and organic agricultural technologies has become part-and-parcel of the political economy of GM foods. (p. 49)

Walters’ (2006, 2010) work includes an examination of the political and economic pressures that countries like the USA place on African countries to accept their surplus GM food as aid. This study also looks at how discursive strategies positioning GM food as the “solution to world hunger” are used to help market GM food.

Looking at palm oil production in Columbia, Mol (2013) sheds light on the “green and social promise of the ‘agrofuels solution’ that generates an array of harms against the people, plant and animal species, and ecosystems of the production regions in question” (p. 244). Like Walters, Mol extends the typical criminological gaze to include issues of social and ecological harm. The paradoxical nature of Columbian palm oil production and by extension the agrofuel industry, in general, is that this “greener” form of energy comes with a list of social and environmental costs. Mol (2013)

points to the ecological impacts of palm oil cultivated in industrial monocultures such as the deforestation of tropical forests from clearing land, as well as the soil, river, and groundwater contamination from an increased use in pesticides, and fertilizers. Also, the expansion of export-oriented agribusiness like palm oil production has disrupted and displaced local production and subsistence practices in Columbia, making it so “communities are no longer able to hold on to their local models of cultivation, characterised by a diversification of cultivated crops interspersed with areas of naturally growing plant species” (Mol 2013, p. 246). A key aspect from Mol’s chapter is the colonial dimension of power (and control, appropriation, etc.) in the context of green issues like agrofuel production and the need to shift the boundaries of harm and crime. In other words, to better understand the negative impacts of palm oil production, a wider criminological lens is needed to better critique the dimensions of power associated with global agribusiness.

Overregulated Activities Regarding Food and Agriculture

A notable example of an environmentally beneficial activity in the food and agriculture sectors that has been consistently overregulated in many countries is hemp. Sold in supermarkets as a health food and used across the world in countless products, hemp is a contentious plant because it belongs to the same species as marijuana. Halsey (1997), Brisman (2010), and Tourangeau (2015) have all identified this crop as unnecessarily regulated and socially and ecologically valuable. Hemp is biologically and chemically distinct from marijuana, yet often experiences similar or identical forms of regulation. Each author points to a different regulatory context, while identifying the same conclusions, hemp is overly criminalized and certain environmental harms could actually be mitigated in contexts where hemp is embraced as an ecologically valuable resource.

Halsey (1997), looking at the Australian context, makes a detailed comparison between two means of producing the raw materials for paper, clear-cutting old-growth forests and cultivating

industrial hemp fiber. In general, Halsey raises the question why, from an ecological standpoint, it is legally permissible to engage in ecologically harmful activities like clear-cutting forests and illegal to cultivate hemp fiber (in Australia at the time) which is ecologically benign in comparison. Engaging with politico-legal constructions of environmental harm, Halsey calls for further clarity regarding the defining and understanding of such environmental harms.

Brisman’s (2010) chapter in the edited volume *Global Environmental Harm* focuses on environmentally beneficial activities that are criminalized, such as pedicab drivers and industrial hemp farming. Looking at hemp in the context of the USA, Brisman points to federal laws which prohibit the growth of hemp, treating it much like marijuana. Questioning its strict criminalization in the USA in comparison to countries in Europe and Asia, Brisman points to hemp’s vast range of uses in food, medicine, fuel, clothing, and building materials, as well as its agronomic benefits like soil purification and weed control.

Tourangeau (2015) exposes a more nuanced overregulation of industrial hemp within the Canadian context. Utilizing an array of theoretical and empirical insights, Tourangeau highlights the complex relationship between regulatory structures and socio-ecological impacts. Currently, Canada permits the licensed growth of industrial hemp, but prior to 1998 hemp farming was prohibited. Tourangeau (2015) examines the Canadian regulations for industrial hemp farming and processing and argues certain circumstances are limiting the industry’s capacity to benefit the environment (through agronomic benefits and lower-impact products like paper). He identifies negative public perceptions of hemp, over restrictive regulatory requirements, and the underdeveloped technological capacity to cultivate and process hemp for fiber, as inherently interconnected with Canada’s long history of hemp prohibition and strict regulation. Like Halsey and Brisman, this article exposes the contradictions of not regulating everyday activities that damage the environment and criminalizing (or heavily regulating) activities that have proved to be environmentally beneficial (or at least benign).

Intellectual property law provides another example of overregulated activities regarding food and agriculture. Goyes and South (2016) criticize Columbia for criminalizing certain traditional ways of life to protect dominant interests. Imprisonment and significant fines are possible for anyone planting or transporting protected seeds without permission – this further marginalizes impoverished communities engaging in small-scale farming practices and positions large transnational corporations as passive “victims” (Goyes and South 2016). According to Goyes and South (2016), “this law exemplifies the way in which the Colombian criminal law and justice system protect dominant interests and hold the satisfaction of the needs of the poor and powerless to the basic minimum” (p. 9). These authors illustrate the value of looking critically at the traditional boundaries of criminology, providing new perspectives to engage with understandings of social and ecological harm.

A Note on Ethics and Green Criminology

Largely written from the perspective of green criminology, various studies over the past 20 years have begun to engage with the idea that criminological investigations need to consider crimes and harms to nonhuman animals and the natural environment. South et al. (2014) explain that “the research agenda for green criminology is based on the objective of studying known forms (and uncovering unknown forms) of deviant and criminal behavior committed against the natural environment and those living beings dependent upon it” (p. 2177). Green criminology’s engagement with harms within and beyond legal definitions of crimes invokes notions of morality, ethics, and human and animal rights (see Brisman 2010). As the boundaries of criminology continue to be challenged by perspectives like green criminology, it will remain essential to acknowledge the role of ethics. For example, Walters’ (2006) article regarding international discourse on genetically modified organisms illustrates how issues of politics, science and technology, and global trade collide with “illegal, unethical and harmful

practices” (p. 26). The above scholarship in criminology, food, and agriculture depicts a unique and effective lens for investigating a range of issues (like food crimes, genetically modified organisms, and illicit drug crops) that engage with ethical dilemmas and the boundaries of crime and harm.

Summary

Criminology plays an important role in food and agricultural ethics, in both traditional criminological approaches regarding breaches of criminal law and the broader lens of green criminology which encapsulates notions of harm beyond strict legal definitions. In this entry, international law, illicit drug cultivation, and “food crimes” are provided as useful examples of criminality and illegality within food and agriculture sectors. These examples are included to showcase the connections between traditional areas of criminology and food and agricultural ethics. The discussion of socio-ecological harms regarding food and agriculture – the harmful activities operating outside of legal definitions – is divided into two categories, those harms which evade consideration within a legal/criminal context and socially and environmentally beneficial activities which are either prohibited or tightly regulated. GM foods/crops and palm oil production have both been investigated by criminologists and are detailed in this entry to expose the environmental harms caused by these products. Adding new dimensions to green criminology, Brisman (2010) suggests we consider “not just activities that hurt the environment and that are unregulated or underregulated, but also activities that are proscribed yet benefit the environment” (p. 184). Halsey (1997), Brisman (2010), and Tourangeau (2015) effectively situate hemp as an overregulated food and crop which has the potential to provide several ecological benefits. As scholarship in criminology, food, and agriculture continues to critique and expand the criminological gaze within perspectives such as green criminology, discussions of morality and ethics will remain essential.

Introduction

Cross-contamination of crops in horticulture is an old phenomenon. Farmers have long experienced genetic material from a neighbor’s fields finding its way into their crops. However, the recent development of transgenic crops, often referred to as genetically modified (GM) crops or

genetically modified organisms (GMOs), is the source of much recent controversy regarding cross-contamination. While many countries have experienced rapid adoption of GM technology, other countries have received it with suspicion and precaution. The varied reactions to GMOs have for the last several decades given rise to conflict and debate on scientific, political, and ethical issues. Cross-contamination has become a frontline in these debates. For example, in 2011, the US Department of Agriculture (USDA) approved GM alfalfa for use. Due to predicted widespread contamination of organic alfalfa with GM material, organic producers felt that the organic status of their crops was under threat. The USDA's decision led to heated debate and litigation where organic and environmental groups were pitted against the government and biotech industry.

The goal of this entry is to identify and clarify the moral and ethical issues arising from the inevitable movement of genetic material between GM and organic and non-GM crops. This goal will be achieved by (1) listing the ethical questions that must be answered if GM, non-GM, and organic producers are to coexist, (2) highlighting the importance of the role that the precautionary principle and the principle of substantial equivalence play in coexistence policies, and (3) discussing two moral theories that can be used to frame the debate over cross-contamination of crops in horticulture.

Cross-Contamination and Coexistence

Like cross-contamination, coexistence is not new to horticulture. However, the advent of GM crops has made coexistence a controversial issue and an area where ethics research is needed. Coexistence roughly refers to different production systems operating in proximity in ways that minimize the negative impacts one system might have on the other. The concept of coexistence is essentially ethical, as it implies a just or fair distribution of the risks, benefits, and costs of coexistence. In the case of GM crops and cross-contamination, coexistence largely means mitigating the amount of

GM material that inadvertently finds its way into non-GM and organic crops. GM material can contaminate non-GM and organic crops in several ways (e.g., seed impurities, cross-pollination, volunteer seeds from previously planted crops, and residual material in harvesting machinery and storage facilities). The extent of cross-contamination can vary greatly depending on many factors. For example, papaya pollen is heavy and does not travel very far, whereas canola-rapeseed pollen is light and can travel long distances. There is, then, a greater threat for cross-contamination in canola-rapeseed than papaya due to pollen flow.

Adventitious presence has long been used to describe the occurrence of impurities (e.g., weed, dirt, and insects) in agricultural products. Since it is all but impossible to harvest a pure crop, maximum levels of adventitious presence (impurities) in an agricultural product can be regulated. The coexistence framework assumes that GM material in non-GM and organic crops can be treated as adventitious presence. It also presupposes that GM and organic crops are in principle compatible, and the way to resolve conflicts is to find the strategies that minimize conflicts created by economic losses due to adventitious presence. However, some opponents of GM technology see transgenes as dangerous pollutants that cannot be recalled once they have escaped into the environment. These opponents do not think it is legitimate to apply the concept of coexistence to the problem of cross-contamination and GM crops; they argue that describing GM material as relatively benign adventitious presence underestimates the risks associated with transgenic technology.

However, the problem coexistence designed to resolve is the possibility that organic and non-GM producers will suffer economic loss due to contamination with GM material. For decades, the number of consumers willing to pay higher prices for organic products has been increasing. Moreover, organic consumers expect, among other things, that organic products do not contain GM material. Simultaneously, production of GM crops has rapidly increased. The growth of these two industries has brought them into conflict. The crux of the coexistence problem, then, is that

organic and non-GM producers hoping to receive a price premium for growing “GM-free” crops can suffer economic losses if their crops become contaminated with GM material from impure seed batches, cross-pollination, etc.

Coexistence and Philosophy

While discussions of coexistence often focus on economic and technical issues, the debate over coexistence is often driven by deeper philosophical commitments. Many who oppose GMOs and agricultural biotechnology see this new technology as unnecessary, inherently risky, and ethically suspect. Further, it is often seen as a means for further advancing the hegemony of industrial agriculture, which they believe is environmentally unsustainable and socially unfair. A Spanish organic farmer summarizes these views, remarking “Why do we need to have GMOs if this technology creates uncertainties, contamination, homogenizes agrarian cultures, the consequences concerning health effects are not clear enough and there are huge questions related to ethical issues” (Binimelis 2008). For these reasons and others, many people and groups have taken a precautionary approach to GM crops: they are assumed to pose a threat to health and the environment until proven otherwise. The International Federation of Organic Agriculture Movements has come out against biotechnology “because of the unprecedented danger this presents to the entire biosphere, and particular economic and environmental risks it poses to organic producers” (Verhoog 2007). On the other side of the debate, biotechnology advocates see GM crops as substantially equivalent to conventional crops. From this view, no agricultural crop is natural or pure, and GM material should not be labeled as an exceptionally hazardous pollutant (Bruce 2003). In addition, scientific promoters of transgenic technology see it as a major breakthrough in the history of agriculture. This is in large part a philosophical debate over the essential nature and morality of organic agriculture versus GM agriculture: it is politically polarizing and not easily resolved.

Coexistence “brackets” these philosophical issues by presupposing a liberal moral philosophy, guided by the principle of liberty and the harm principle. The principle of liberty requires the state to be neutral on questions of moral and philosophical significance to individual people and groups, i.e., questions about the good and the good life. It allows individuals the freedom to pursue their personal convictions on how to best live their lives, unless they harm others. At this point, the state can no longer remain neutral and has an obligation to intervene to prevent harm. The coexistence framework, then, attempts to be politically neutral on the moral and metaphysical dispute between organic and GM agriculture. Coexistence as a liberal concept means creating a system that is fair to a plurality of cropping choices.

Coexistence and Ethical Questions

Due to the growth of the organic and GM industries and the problem of cross-contamination, the liberty of organic and non-GM producers has come in conflict with the liberty of GM producers (Verhoog 2007). While the principle of freedom of cropping requires the relevant government agencies to be neutral and fair in creating a regulatory environment, in reality, neutrality and fairness are difficult to achieve. Regulations aimed at coexistence can easily prejudice one agricultural system over another. Furthermore, regulations do not admit straightforward technical solutions; regulatory frameworks for coexistence rest on moral and political decisions that distribute risks, benefits, and burdens. For instance, setting of standards (or not) for levels of purity in organic and non-GM crops requires compromise.

Many organic farmers and consumers hold that the integrity of organic products requires them to be 100% GM-free. However, if a GM crop is grown near a sexually related non-GM or organic crop, some contamination is all but certain. It is not economically practical to keep crops in complete isolation. Coexistence requires organic farmers and consumers to compromise and accept some level of GM adventitious presence. But if

the levels of purity are set too high, the measures required to mitigate cross-contamination are too costly to make coexistence possible. Coexistence removes the liberty to choose completely “pure” organic products, and stringent standards of purity remove the liberty of farmers to choose to grow GM crops.

For policymakers to navigate this ethical dilemma, they must answer the following types of questions: What levels of GM material in organic and non-GM crops are acceptable? What measures should be implemented to meet these standards? Who has the duty to implement these measures? Should the burden be on GM farmers to “fence-in” their crops or should the burden be on the non-GM and organic growers to “fence-out” GM material? If contamination occurs, how should organic and non-GM producers be compensated for economic losses? The USA and the European Union are approaching these questions very differently, which has led to contrasting approaches to coexistence. To understand the ethical issues here, it is instructive to contrast these to two approaches.

Coexistence in the European Union

The EU is officially committed to coexistence and freedom of cropping. However, the adoption of the precautionary principle to regulating biotechnology seems to have created an environment where some feel the burden on GM is too large. The EU has adopted a two-tier approach to setting thresholds for GM adventitious presence in products. In regard to the question of thresholds, the EU has regulated that there is a 0.9% limit applied to approved GM products and a zero tolerance threshold applied to unapproved GM products. This is a fairly stringent standard for purity – the USA has no maximum standard, and Japan’s threshold is 5%. The 0.9% limit, then, is a practical, political compromise within the European context that has left some people on both sides of the GMO debate unhappy.

Questions about measures used to meet these standards and who has the duty to implement them are left to the EU’s member states progress

toward coexistence varied across Europe. For example, Spain has made the most progress on implementing a legal framework for coexistence, whereas Austria has sought to remain GM-free. There are several techniques that can be used to mitigate adventitious presence below the 0.9% threshold, for example, creating buffer zones around crops, staggering the planting of crops so flowering occurs at different times, and cleaning harvesting and processing machinery and storage facilities.

The question on compensation for financial losses due to GM contamination is also decided at the level of the EU’s member states. Because there are so few GM crops grown in the EU as of 2013, this is not a significant problem. However, the liability schemes throughout the EU place the burden on the GM industry and GM growers. If an organic or non-GM farmer can show that contamination leading to economic losses occurred due to negligence on the part of a neighboring GM farmer, that GM farmer can be held liable for full restitution of losses. If contamination occurred accidentally, the organic or non-GM farmer would be reimbursed through a compensation fund. The mechanism for endowing the compensation fund varies by member state, but in all cases, compensation comes in some way from GM growers or the GM industry.

In Europe, coexistence has become “a focus of opposition to GMOs,” since it “arguably constitutes the last rampart against the full commercialization of the GM crops that have now passed through the authorization stage” (Bodiguel et al. 2010). Several authors have objected that the way coexistence is being implemented in the EU is placing an unfair burden on the biotech industry and those who wish to grow GM crops. They assert that many countries’ approach to coexistence is constraining farmers’ liberty to grow GM crops. In the journal, *Nature Biotechnology*, a 2008 article asserts that EU is going to “ridiculous lengths” to prevent cross-contaminations (Ramessar et al. 2010). In the same journal, a 2010 article wonders if the coexistence policy in the EU, which was intended to remove the moratorium on GM crops, was simply a backdoor way of reinstating the moratorium (Devos et al. 2008).

One major complaint is that some countries in Europe require excessively large and inflexible distances between GM and non-GM crops to prevent cross-pollination. They claim that these isolation distances are not scientifically justified and make it too difficult and expensive for farmers to grow GM crops (Ramessar et al. 2010). Ramessar et al. assert:

The scientific process appears to have been discarded by the EU and its member governments in the case of GM agriculture. Not only are the thresholds for adventitious presence far stricter than for conventional crops, but the isolation distances implemented to achieve such thresholds are arbitrary, excessive and appear to be politically motivated rather than to reflect scientific reality. (Ramessar et al. 2010).

In summary, some argue the way coexistence is being implemented in the EU, specifically, the large isolation distances required by some member states, is “jeopardizing farmers’ freedom of choice to grow GM crops” which “contradicts the European coexistence objectives” (Devos et al. 2008).

Coexistence in the USA

Like the EU, the USA is officially committed to coexistence and freedom of cropping. But unlike the EU, the USA rejects both labeling GMOs and establishing thresholds for GM adventitious presence in organic and non-GM products. This is largely because the USA applies the principle of substantial equivalence to biotechnology, whereas the EU applies the precautionary principle. The argument against labeling asserts that labeling GMO crops implies that GMOs are different than traditional crops and may pose greater risks to human and environmental health, which contradicts the principle of substantial equivalence. Furthermore, because organic standards in the USA are process based, as long as GMOs were not used in the production process, GM adventitious presence does not violate standards, and products containing GM adventitious presence can be labeled USDA Organic. Thus, on the issue of threshold levels of GM material in organic product, the relevant US regulatory

agencies are currently silent. For many organic advocates, regulatory silence does not equal neutrality. They believe it is creating a system that places an unfair burden on organic and non-GM producers to achieve coexistence.

In the absence of government labeling and mandated thresholds, a nonprofit, natural foods advocacy group has stepped into that role. To honor consumers’ expectations and the philosophical commitments of organic producers and wholesalers to exclude GMOs, organic companies are starting to participate in the Non-GMO Project. The Non-GMO Project is a third-party verification certification program that sets standards for detection of GM material and reduction of the risk of cross-contamination. The Non-GMO label follows the EU’s 0.9% threshold. Crops exceeding this level cannot be certified non-GMO. Many large organic companies are participating in the program and refusing to purchase organic products that do not meet this standard.

Because the USDA does not label GMOs, there are no regulations mandating measures to prevent GM adventitious presence. However, organic consumers still have an expectation that organic products are “GM-free.” This means that the burden of preventing GM contamination falls on organic and non-GM producers. The argument for placing the burden on organic growers and non-GM producers to “fence-out” GM material asserts that because these farmers receive a price premium for organic and non-GM crops, it is their duty to take the necessary measures to meet the standards of their contracts. If that requires minimum levels of GM material through non-GMO certification or by meeting EU standards, it is the grower’s responsibility to assure they meet those levels. In the USA, adventitious presence is a risk that the organic and non-GM farmers must accept. To mitigate this risk, organic farmers must learn if their neighbors are growing sexually compatible GM crops and take measures like creating buffer zones and staggering planting to mitigate GM contamination.

Many organic and environmental groups believe that the current system in the USA is unfair. They argue that the biotech industry and GM farmers should bear more of the burden for

keeping GM “pollution” out of organic and GM crops. For example, in a 2010 position paper titled “GMO Contamination Prevention and Market Fairness,” the National Organic Coalition asserts that “Farmers who seek to avoid GMOs must not continue to be solely responsible for contamination prevention and/or be forced to give up growing certain crops. For this to happen, direct government intervention is needed to protect livelihoods and local economies.”

In 2012, the USDA Advisory Committee on Biotechnology and Twenty-First Century Agriculture (AC21) published “Enhancing Coexistence,” a report to the Secretary of Agriculture that sheds light on the debate over cross-contamination and coexistence in the USA. The Advisory Committee is composed of a diverse group of stakeholders representing both the organic and GM sides of the controversy. The consensus recommendations focused on measures to facilitate coexistence and compensation. Importantly, the report affirms the principle of substantial equivalence as a foundational premise for regulation, stating that “the presence of genetically engineered crops does not create risks that are novel in agriculture” (AC21). (Several committee members in the comment section objected to this premise and referred to the precautionary principle instead.) In general terms, the report places the major emphasis on educational outreach to farmers and others involved in the food production system as a means of achieving coexistence. These efforts would aim at building farmer-to-farmer cooperation and local voluntary solutions. In addition, the report recommends further research on promoting coexistence in US agriculture. Interestingly, those on the committee associated with the agricultural biotechnology industry had far fewer reservations with the report than those who were associated with the organic industry. In the comment section, the opposing committee members voiced that these recommendations favored the GM industry. One member commented that “‘successful’ coexistence means that the USDA must take its finger off the scale in favor of biotechnology.” This member felt that the biotech industry and GM producers have “no skin in the game, and the financial burdens remains

squarely on the backs of non-GMO agriculture.” Several who signed the consensus report did so to support the effort as a “step in the right direction,” but felt that it fell far short of recommending a system that would be fair to organic and non-GM farmers. One member felt that the “[the committee] did little to allocate responsibility for minimizing and preventing problems.” Another commented that “The farmer choosing to grow non-GM crops should not be expected to bear the primary responsibility and costs for avoidance strategies and/or possible market loss due to something they have no control over.” In summary, the above comments reflect the opinion of many involved with the organic industry in the USA: the system is unfair to organic growers, and the report’s recommendations for education, voluntary cooperation, and further research fall short of distributing the burdens of coexistence fairly.

In regard to the question of compensation, the report recommended that “compensation mechanisms should be modeled on existing crop insurance.” This means that organic and non-GM producers would bear the burden of buying crop insurance to be protected from the risk of financial loss due to GM adventitious presence. The report also recommends that the government take steps to keep the insurance affordable. While all but one member signed the consensus report, there was widespread disagreement on the compensation mechanism.

In general, the reaction to the AC21 report from the organic industry was largely negative. There was a feeling that both the coexistence recommendations and the compensation mechanisms favored the biotech industry and GM growers.

The contrast between the EU’s and US’s approach to coexistence makes clear that the decision to apply the precautionary principle versus the principle of substantial equivalence is a watershed issue. To review, the precautionary principle places a burden on innovators to demonstrate that new GM crops are safe. GM crops are treated differently than traditional crops because they are seen as creating novel health and environmental risks in agriculture. Substantial equivalence assumes that GM crops pose safety threats that

are similar traditional crops. In broad terms, GM crops should not be treated differently than traditional crops. As demonstrated above, using the precautionary principles or the principle of substantial equivalence leads to conflicting answers on the four basic coexistence questions regarding setting threshold levels, instituting mitigation practices, assigning duties, and providing compensation.

Despite the large body of literature on cross-contamination and coexistence, more research needs to be done on ethics of applying the precautionary principle versus substantial equivalence to this issue. Further, more inquiry and discussion are needed on the ethical issues arising from the four basic questions (listed above) requisite to achieving coexistence. The final issue that requires attention is the moral theory used for framing the conflict over cross-contamination, which is the subject of the final section.

Two Moral Theories for Framing Cross-Contamination

The long-standing debate in political philosophy between liberalism and communitarianism provides a lens through which to view the controversy over cross-contamination and an area for further ethical research.

As has been seen, the notion of coexistence is grounded in liberalism as it is premised on freedom of choice, state neutrality, and the harm principle, thereby leaving the difficult moral and metaphysical debates between GM and organic agriculture for individuals to decide. By way of contrast, the moral theory of communitarian holds that it is not possible or desirable for the state to remain neutral on questions of the good or the good life. It asserts that liberalism's focus on individual choice misunderstands the nature of the relationship between human agency, morality, and politics. For communitarians, political structures and human character are ultimately shaped by conceptions of the good and the good life. Below the surface of the controversy, the debate about cross-contamination is driven by deep disagreements about food, agriculture, and the good

life. The coexistence framework may not be adequate to resolve these disagreements.

Individuals on both sides of the debate argue that coexistence between organic agriculture and technologically driven, intensive agriculture, which includes biotechnology, is ultimately not possible or desirable. On the one side, advocates for biotechnology have argued the organic movement is a dangerous impediment to the scientific and technological progress needed to feed a rapidly growing world population sustainably (Trewavas 1999, 2001). This position is more than a technical argument about solving the equation of production and population through innovation: it entails a vision of the relationship between science, technology, food, agriculture, and the good society. On the other side, organic advocates argue that biotechnology furthers an unsustainable and unjust agricultural system. Advocates for organic farming, agroecology, and neo-agrarianism hold that GMOs are incompatible with a vision that harmonizes the relationship between food, agriculture, the environment, and the good life. One of the central points of contention between these competing visions of agriculture and the good life is the goal of cultural and biological diversity.

Technologically driven industrial style agriculture has greatly increased crop yields. Production and efficiency are the central values associated with of this vision on the relationship between food, agriculture, and the good life (Thompson 1995). However, in increasing efficiency, this approach has reduced cultural diversity (e.g., the preservation of small farms and farming communities) and crop diversity, both considered as goods by organic farmers and agroecologists (Altieri 2005). The norms inherent in these contrasting visions of food and agriculture may be incompatible. On this deeper level, then, the cross-contamination controversy is about the meaning and significance of agriculture and food. If this is true, then communitarian moral theory might be a more profitable way of framing and investigating this controversy. Therefore, along with research on the ethical issues arising from the application of the concept of coexistence, another line of research would question the liberal framework

that undergirds coexistence using communitarian moral philosophy.

Summary

This entry describes the controversy over cross-contamination of crops in horticulture due to the conflict between organic, non-GM, and GM crops. It also identifies the central ethical questions that need to be answered to make coexistence between these different cropping systems fair or just. In addition, it points out the importance of the precautionary principle, and the principle of substantial equivalence has played in providing alternative perspectives in distributing the risks, burdens, and responsibilities of achieving coexistence. This was done by contrasting the EU's and the US's approaches to coexistence. Finally, this entry suggests that research into alternative moral theories, liberalism, and communitarianism and the controversy over cross-contamination could shed light on the nature of this important moral and political debate.

Introduction

Cuba has a complicated history which has shaped its landscape and impacted its people in many ways. Due to its geographical location as an island in the Caribbean it has had an extraordinary level of dependence on its lands and natural resources for commerce and trade as well as support of its people. Cuba's landscape is highly heterogeneous including high mountains, steep grades, long low grassy fields historically used for grazing animals and wide flat expanses with rich soils that have been used extensively for agriculture. The land use practices on the island have varied quite significantly over time ranging from a focus on cattle, tobacco and sugar. Cuba's recent agricultural history is intricately linked to its international relations with the Soviet Union as well as that country's collapse in 1990. Cuba's total dependence on the Soviet Union for such a long period of time made the period after 1990 especially difficult for the Cuban people. There is also the ethical side of the Cuban people's struggle linked to food security issues.

To fully understand the complexities of Cuban agricultural history and its ethical implications for the Cuban people and other involved parties, it is necessary to provide a brief history and evolution of agricultural land use before examining the important ethical issues. First, the major significant foci of Cuban agriculture in terms of key imports and exports through time will be discussed. Second, the scientific advances that have been made in organic agriculture due to lack of expensive pesticides and herbicide availability will be considered. These advances have been necessitated as a result of an absence of funds to import chemical treatments for pests and fungi infestations. Third, the ethical dimension of Cuban agriculture in terms of modernization possibilities and who is partnering with Cuba to improve their food security is examined. Finally, recommendations are offered for a way forward and lessons learned in Cuba for the people and the potential political paths that Cuban leadership could take to lead their people towards a more stable food economy.

Background and History

Significant Historical Foci of Cuban Agriculture

Cuba's import and export history begins with the establishment of towns along its coast in the early 1500s. The first settlements were established by Diego Velázquez, a lieutenant to the Governor of Hispaniola: Nicolas de Ovando. Nuestra Senora de la Asuncion (now Baracoa) was the first settlement from 1511 to 1512. From 1512 until the mid-1700s most new cities were established near Havana, although Velázquez selected Santiago de Cuba as Cuba's first capital because it had an outstanding harbor and was near the major trade routes at that time (Gebelein 2012). During this early colonization the initial settlements were either near ports or close to natural resources that could be easily transported to a port city. It was also during this time that one of the first major examples of human subjugation occurred on Cuba. The Spanish needed labor to exploit their newfound resources in Cuba and the native Indian population was proximally, if unwillingly, available. The labor needed at that time was diversified and hands were needed to plow and maintain the agricultural sites for the settlers in that area.

Velázquez first enslaved the local Indian populations and forced them to labor for the Spanish. A local chieftan who had seen the inhumane methods Velázquez employed to subdue and exploit the Indian population in Hispaniola attempted to lead an opposition against Velázquez failed when he was caught and burned at the stake. Over the next several decades the Indian population fell because of illness passed on by the settlers, escape from the island, integration into the settlers' population, death due to brutal slavery practices, or from revolts (Gebelein 2012).

Tobacco was one of the crops grown before Spaniards settled the island. Columbus witnessed the Cuban Indians smoking it before he knew what it was and was a regular trade item between the Spaniards and the Indians. The Spaniards did not recognize its potential until well after colonization was established. They discovered the further west tobacco is grown, the better the tobacco. Drawing a quality line from east to west the

tobacco industry has the *Mayari y Gibara* in the Oriente Province. One of the factors that separate tobacco from other crops is that it is labor intensive to grow. There are many small and time consuming steps to cultivating a quality tobacco plant. A second and far more important example of high maintenance crop is, of course, sugar.

Sugar was not immediately impactful on the Cuban landscape or to its economy. Despite the fact that sugarcane was introduced to the island in the early 1500s, it was not until 1590 that sugar mills were introduced to produce commercial sugar. Sugar then became a very popular export but the fact remained that it was extremely labor intensive to get the final product to market. From clearing forested area to planting, maintaining and processing the cane took many laborers and much time. Herein was the problem of available ready labor. However, when the British captured Havana they also introduced black slavery to Cuba. These thousands of African slaves became the labor force that Spain needed to support an increased production of sugar. This and other related events began a chain reaction in Cuba in response to an increase in labor force and a rising demand for Cuban products.

The demand for sugar has not been steady or altogether predictable. The rise and fall of sugar has directly impacted Cuba's foreign relations, the economic security of the island and its people as well as the stability of the government and its ability to provide for its people. For example, sugar prices rose steadily in the early 1900s, and by 1913, the majority of the U.S. investment in Cuba was in its sugar valued at approximately 200 million U.S. dollars. Cuba was also producing 12% of the world's sugar supply at this time. The First World War caused a dramatic increase when The English Royal Commission began importing raw sugar from Cuba. This trading relationship lasted throughout World War I. By 1918 Cuba had the largest sugar enterprise in the world, however from June 1920 to December 1920, the price of sugar dropped approximately 14 cents per pound due to European competition. This was devastating for the Cuban economy, laborers left, and banks on Cuba closed; forcing President Menocal to declare a moratorium (Thomas

1998). Things did not get much better as years passed. The United States' share of the Cuban sugar market dropped from almost 50–25% by 1933. These conditions, not surprisingly, led to economic crisis on Cuba with more mills closing, employment opportunities in Cuba fading, labor fleeing the island for better opportunities elsewhere, and a dismal international market reflecting bad financial times for the island. Cuba's economy then began to improve while its people, particularly its poor, began a slow decline. When Batista returned for a second term as Cuba's president, foreign investors began reinvesting in Cuba. Mining operations increased with substantial U.S. investment for extraction of cobalt and nickel. Tourists began returning to Cuba and the tourism industry became one of Cuba's most important sectors of revenue. Under Batista the cattle industry increased to compete with the highest ranking cattle industries in Latin America. Despite this, for 9 years, until 1958, sugar accounted for 85% of Cuban exports. This monoculture approach was a huge weakness in terms of being totally dependent on the international market's price fluctuations. The second major flaw in Batista's economic structure was the majority dependence on the United States for imports and exports. Approximately 75% of Cuban imports came from the United States and almost 65% of Cuban exports were consumed by the U.S. market (Suchlicki 2002). Most of Cuba's people did not fare well under Batista's rule either as he ultimately befriended and rewarded the largest sugar plantation owners resulting in a larger disparity between rich and poor Cubans, continually exploited Cuba's many commercial investments including agreements with the American mafia that were linked to nefarious businesses based in Havana (Olson 2000). He also quelled riots and public discontent with violence and murders using his secret police to instill fear into a populace already discontent from continual economic downturns and his oppressive regime. Cuba was poised for another revolution.

When Castro took power from Batista in 1959, major changes took place that directly and fairly quickly impacted the Cuban economy and its people. One of the first and most devastating to the

economy was the quick erosion of the U.S. Cuba political trade agreements. For the first few months of Castro's presidency, he continually reiterated his opposition to U.S. financial interests and control of assets in Cuba. However, he allowed business to continue as usual during this period. During this time the Eisenhower administration waited to see what would ultimately become of Castro and his policies, and had no real response to Castro's condemnation of the United States' involvement in Cuba. Yet the relationship between Cuba and the United States became far more strained when the Agrarian Reform law was enacted. It initiated agricultural expropriations which the U.S. formally objected to but these complaints had no influence. The Reform Law was quickly followed by other attacks on U.S. foreign investments including mining and petroleum interests. The relationship between the two countries deteriorated further when, in February 1960, Castro signed a key trade agreement with the Soviet Union that stated Cuba would receive oil for sugar. However, a few months later both U.S. and English refineries declined to process Soviet oil. Concurrent to this, the U.S. president was granted authority to curtail foreign sugar quotas as his discretion. In a reactive retribution, Castro nationalized those oil companies that had refused to process the Soviet's oil. One month later the U.S. eliminated its request for its remaining order of sugar imports from Cuba for the year. Castro continued to nationalize all oil companies on Cuba for the next few months. In retaliation the U.S. pronounced an embargo on most goods exported to Cuba, withdrawing its American ambassador to Cuba shortly thereafter (Suchlicki 2002). The U.S. amended the Sugar Act of 1948, which has given preferential treatment to Cuba is the form of the majority of the sugar market quota, to *only* restore Cuba's sugar quota if it returned to a "free world", or free of socialist ideologies. Shortly thereafter in July 1960 the Soviet Union stated its willingness to buy the U.S. quota share of sugar. In fact, the Soviet Union and Cuba came to an agreement whereby the Soviets would buy at least five million tons of sugar at a much higher price of US\$125/mt (5.67 cents per pounds) (Alvarez

and Castellanos 2001). Additionally, since Cuba no longer had access to the imports it needed from the U.S. in terms of farming fertilizers, equipment, food, et cetera; it now began to depend largely on its new trade relationship with the Soviet Union for these requirements.

One of the key things to note here is that without the Soviet's saving relationship with Cuba, Castro would have been in dire straits to provide for his people and find such an all inclusive importer of Cuba's goods. This situation should have highlighted the fact that dependency on a monoculture is not safe or predictable in a world market especially when political ties become strained. Cuba's major exports in the early 1960s were sugar, tobacco, nickel and rum, with sugar eclipsing all others. Instead of diversifying however, and heeding this clear economic warning, Castro continued with a focus on increasing sugar production and exports. In fact, not only did Cuba not diversify its exports, it increased its sugar quota markets to include Eastern Europe, China, and other countries which added to the total export demand. These new demands amplified sugar output levels to just over eight million metric tons of sugar per year. Castro's economic plan was to achieve ten million metric tons of sugar by 1970. This did not happen mostly due to his miscalculation of agricultural production potential and underestimation of essential manufacturing investment (Alvarez and Castellanos 2001).

The Special Period

The next phase of Cuban agricultural history was spurred by the fall of the Soviet Union and the strengthening of the United States blockade. With the Soviet Union in complete disarray, Cuba lost its greatest trading partner. This was underscored by the fact that 85% of Cuban trade had previously been with the socialist bloc of Mutual Economic Assistance (CMEA) and almost all of those contracts were done in nonconvertible currency. The combination of these things was devastating to the Cuban people because commercial trade fell by more than 90% after the fall of the Soviet Union. For example trade with Cuba dropped from \$8.7 billion in 1989 to \$750 million in

1993. Furthermore, Soviet oil imports to Cuba plummeted 90% from 13 million tons in 1989 to 1.8 million tons in 1992. Every basic foodstuff, grain and all previously available consumer goods became scarce or unavailable and the importation of raw materials and spare parts critical to multiple industries in Cuba became completely unobtainable. Impacts to agriculture were also significant. Fertilizer imports to Cuba declined 80% in only a few years. The consequences of these combined events led quickly to fuel shortages resulting in closed factories and many industrial plants as well as a serious shortage of consumer goods (Gebelein 2012).

This phase was coined the Special Period (*periodo especial*) and lasted from 1990 to 2000. Farming equipment such as trucks and tractors were replaced by livestock and farm animals since there was no further access to spare parts or fuel. Out of necessity there was a much greater focus on maximizing organic farming methods such as IPM (Integrated Pest Management), and vigilant crop rotation to get the most out of soil nutrient retention and minimize weed invasion (Gebelein 2012). However, despite these efforts, this period was marked by economic depression, agricultural stressors, and a forced end of a dependence on the Soviet Union. Cuba became truly marooned from the global marketplace when trade relations with the Soviet bloc disappeared (Pérez 1995).

Cuba's isolation was not complete however. In 1992, the United States issued an executive order which prohibited ships that had traded with Cuba to enter U.S. ports. This resulted in a major decrease in the number of countries (and companies) willing to conduct trade with Cuba (Thomas 1998). Compounding an already serious situation, that same year the United States passed the Torricelli Bill, also called the "Cuba Democracy Act." This act required that subsidiaries of U.S. companies that operated in third countries were not allowed to trade with or invest anything in Cuba. If a country were caught doing so in violation of this act, the U.S. stipulated that it then had the right to withhold debt relief, free trade agreements and any economic assistance with countries that gave aid to Cuba (Pérez 1995).

This situation became quite dire very quickly for the Cuban people.

The Green Revolution

Just before the crash of 1990, Cuba had established steps towards its Green Revolution, with the assistance of the Soviet Union. It has also been called the "Soviet Agricultural Revolution" as well due to the Soviet assistance in this project (Warwick 2001). This period occurred from 1984 to 1991 and the goal was, not surprisingly, focused on increasing agricultural output by permitting farmers to grow crops in areas that had been previously protected by law. Sadly, this led to extensive forest clearing and the destruction of other native vegetation communities that had previously been protected and left undisturbed. The Green Revolution was mostly focused on the expansion of sugarcane cultivation, again adding to the dependency on the Soviets for their sugar exports, and increasing the need yet again for imported pesticides, farm equipment and oil, and hybrid seeds (Rosset 1997; Warwick 2001).

Reanimation of the Economy

The final period of discussion is the Reanimation of the Economy which also began in the late 1990s lasting until, some would argue, 2011. Here is the first inkling of hope in the transition from the heavy dependence on chemical intermediates to more natural biological agents in the agro-ecological conversion process that scientists have exploited for large scale farming areas (Funes 2002; Febles-González et al. 2011). There were also successful transitions to organic pesticide management approaches and use of organic nutrients for fertilizer as well. In spite of these advances, in 2007, there were only approximately 4.9 million acres of land actively cultivated, even though there were just over 9.8 million acres of fertile land available for farming. The Cuban government made massive efforts to encourage farmers to plant food. Nonetheless this did not last throughout the Reanimation period and was largely unsuccessful. From 1999 to 2007 Cuba's total cultivated land fell 17.5%. While this decrease is an island-wide average, there were decreases in every province of

cultivated lands during this period. Thus while Cubans may have had access to fertile lands and wanted to farm them, they had no access to the necessary farming tools or resources to produce any kind of crop yield. The Cuban government had set completely unrealistic goals with the Reanimation Proclamation and the Cuban people had no way of achieving these lofty aspirations (Febles-González et al. 2011). However, while this historical background has painted a dire picture of the conditions in Cuba regarding food security for its people, there have been impressive innovations and creative movements by the government and its people to improve conditions.

Scientific Advances in Organic Agriculture Due to Lack of Expensive Pesticide and Herbicide

After such a historical downturn of the economy based largely on heavy foreign dependence and a commercial monoculture, Cuban agriculture has refocused on sound agro-ecology practices. The main goals of this include fostering rural employment, strengthening the social network between rural and urban dwellers, utilizing appropriate technologies to increase productivity and above all achieve food security and greater independence from foreign countries (Febles-González et al. 2011). There have been many attempts, some successful and some not, of Green Farming approaches. Interestingly, these greener, organic approaches were in existence for many decades, but they were never mainstreamed because of dependence on the soviet imports for pest control, herbicides and pest management. For instance, the parasitic fly *Lixophaga diatraeae* was used against a cane boring pest in approximately 95% of the cane on the island since 1968. Predatory ants (*Pheidole megacephala*) were used in the 1980s to control the sweet potato weevil *Cylas formicarius*.

IPM (Integrated Pest Management) was integrated into national policy in 1982 but not mainstreamed until the beginning of the Special Period. IPM successfully uses a number of specific insects for weed control and plant disease approaches to reduce reliance on chemical pesticides. For example Cuban scientists have created

pesticides which are extracts from plants like the neem tree. At the close of 1991, roughly 56% of Cuban agriculture was treated using organic biological controls (Gebelein 2012). Another example of better agro-ecological practices is crop rotation. During the height of the monoculture boom, this was not done much throughout the countryside. One of the little known reasons for rotating crops is to out compete the weed community. For example planting sorghum or corn, after its harvest, planting potato, harvest the potato, and then back to sorghum or corn again. Planting these crops in this particular order in combination with natural herbicides, was discovered to prevent feverfew or Mugwort (*Parthenium hysterophorus*) and additional Dicotyledonous annual weeds (Rosset and Benjamin 1994).

Ethics in Cuban Agriculture

The Cuban People and Potential for Food Security

The history of agriculture and food security in Cuba demonstrates that the Cuban people have been victims of failed leadership in and political enemies of the socialist state of Cuba. It is a testament to them that IPM has succeeded in several types of crops. More recently, the leadership of Cuba has realized that in order to feed its people and succeed without total dependence on another country, it must *involve* its people in land ownership and provide the tools and policies necessary to support local efforts rather than a top down approach. The Soviet-style, large-scale food production system worked fairly well with the substantial economic backing of the Soviet Union and importation of farm machinery, pesticides and herbicides that were not available internally. However, when these resources and support disappeared the people suffered in terms of obtaining basic nutritional needs for a very long time. In 1990, Castro further defined the Special Period as the Special Period in Peacetime, which proved to be the basis for a new structure to support basic food necessities for the Cuban people. More specifically, this was the turning point for Cuba towards a low external input production,

and an organic agro-ecology approach which included reconstructing Cuba's agricultural infrastructure to break up large scale state farms into smaller entities under more direct supervision by local managers. This new management approach also included government support of private sector farmers' markets and the development of urban agriculture in the cities, towns and more rural areas. Involvement of the people was also realized with attention to a new importance placed on farmer-to-farmer exchanges, on farm research and agro-ecological training for scientists and farmers (Rosset and Moore 1997).

Ethical Lessons Learned

There are two main lessons we may draw from Cuba's agricultural history. The first is couched in political dominance. Given the history of Cuba's decision to be completely dependent on a monoculture of sugar, it eventually led to almost total dependence on the Soviet Union to sustain an inflated economy. The economic success was not sustainable due to inflated sugar prices in exchange for Cuba's agricultural imports. The crash of the Soviet Union put the entire Cuban economy in dire straits for many, many years. The reason such dependence is linked to ethical concerns for Cuba's people is food security. Because of poor long-term planning by the Cuban government, its people have suffered and have had to quickly develop ways to sustain themselves at bare minimum standards of living and caloric daily intake. The people have also been prevented by Castro from expanding into revenue generating opportunities for themselves to increase their standard of living by a dictatorship of forced socialism. The important links here between Cuba's agricultural history, its leadership and its people is an issue of economic equity. There should have been an effort made towards a reduction of poverty through improved access to such entrepreneurial opportunities as well as access to improved farming technologies and sustainable practices. Unfortunately this did not occur and inequity increased dramatically between Cuba's few rich and many poor. Having first the United States and then the Soviet Union as a primary

benefactor did not ultimately prove viable in the long term. Therefore the alternative is a more sustainable way forward.

The second major lesson is addressing the lessons learned and potential application of those lessons in the future. How has Cuba begun to recover from this failed status? Currently, while smaller scale growing culture is increasing in the farming communities, urban agriculture is a fast growing segment of getting nutritional requirements to the Cuban people. While urban agriculture is not the only answer to the nutritional deficiencies of the Cuban people, it is fast becoming a sustainable solution to food security in Cuba and indeed is encouraged by the government. And while the allowance of this practice is not the solution to Cuba's food crisis, it is playing a large part in Cuba's recovery from the crisis caused by the collapse of the Soviet Union (Allen 1999).

The Recognition of Change

The Grupo Nacional de Agricultura Urbana (GNAU) now recognizes and supports four major types of urban agriculture. The first is called *patios* that Cubans are encouraged to plant for their own households, although they are allowed to sell surplus vegetables and fruits. As of 2012 there were 400,000 *patios* officially registered which entitles the owner to reduced prices on plant supplies. *Parcelas* are unused parcels of land that an individual is granted access to plant and may keep for his own as long as a certain level of crop production is met each season. There are also the *organoponico*. This unit is for production in long rectangular plots approximately 1 m by 15–30 m. They are slightly raised beds. These units have irrigation, superior soil and other modifications beyond the normal plot of land given to an individual. Finally, there is *huertas intensiva* (intensive garden), which are comparable to the *organoponico* except they are at ground level and are not raised. The important things to note here is the first two are recent evolutions of space that recognize the importance of the self-supporting individual. This is a stretch from the total domination of agriculture several decades ago. The second

two have been in existence since the 1980s and their success is a tribute to their continued existence (Koont 2011).

Summary

Cuban issues of food security and ethical concerns are vastly complex. The history alone has occupied hundreds of pages in journals, books and other scholarly works. The overall lesson learned here is based in diversification of economic interests and remembering to empower the individual as well as the collective. When Castro took power, he took back the capitalistic stance that had controlled Cuba's interests for so long. However, history seems to have proven that he swung too far towards total control over his people, the land and focused too closely on a monoculture that proved ultimately to be the country's demise due to the trade of capitalism for a total dependence on a country with similar values. The background and way forward presented here are only a small pixel of a portrait that we hope, over time, paints a picture of sustainable living, a healthy population and independent country that can stand strong and support its people.

Culinary Cosmopolitanism

Tammi Jonas
Cultural Studies, University of Melbourne,
Melbourne, VIC, Australia

Synonyms

[Gastronomic multiculturalism](#)

Introduction

The meaning attributed to practices of consumption and production of food that are deeply tied to identity and community. While “food adventuring” or “culinary tourism” may be forms of colonialism and means of accruing cultural and social capital, they may also contribute to the formation of cosmopolitan subjects. This entry provides an overview of the history of cosmopolitanism as a philosophical construct and moral project and details the ways in which cosmopolitan engagements with multicultural foodways can be spaces of “hopeful intercultural encounters.”

Definition

Cosmopolitanism is an openness to and willingness to engage with cultural Others. *Culinary* comes from the Late Latin *culina*, meaning “kitchen,” derived from Classical Latin *coquere*, or “cook.” The “culinary arts” are popularly understood to be the art of cooking, in this case, a fine art, or sometimes equated with *haute cuisine*.

Culinary cosmopolitanism can be understood to refer to practices of consumption and production (provisioning, cooking, eating, and feeding) that are linked to the development or manifestation of cosmopolitan attitudes. Although culinary cosmopolitanism is sometimes used synonymously with “gastronomic multiculturalism,” the latter is simply descriptive of practices of dining within multicultural settings, whereas the former is posited as a moral project of sorts, a conscious aspiration to genuine openness and engagement with cultural Others.

A History of Cosmopolitanism

The concept and promotion of cosmopolitanism are generally credited to the Cynics and the Stoics before being taken up again by Kant during the Enlightenment. Diogenes, considered one of the founders of Cynicism, when asked where he came from, said, “I am a citizen of the world [kosmopolitēs],” thereby flouting the importance

and exclusive rights of citizenship of his time. Kant’s moral cosmopolitanism posits that all human beings are worthy and deserving of moral concern and that they are also all capable of understanding this principle and creating a universal system of law to which all nations should ascribe.

Arising out of this moral universalism is “political cosmopolitanism,” which subsequently establishes cosmopolitanism as oppositional to nationalism (Hannerz 1990). According to this formulation, one cannot simultaneously be both nationalist and cosmopolitan or form strong attachments to both the nation-state and the world. If one is a cosmopolitan and therefore a “citizen of the world,” then how can one also be committed to what is essentially an exclusive particularism (the nation)? However, this concept has been critiqued on a number of points, for example, as “rootless” (and so unable or unwilling to engage with the location in which they mostly exist, where they might hope to do the most “cosmopolitan good” were they more attached) and as “deracinated intellectuals” and elitists (Robbins and Cheah 1998; Beck 1998; Werbner 2008; Nowicka and Rovisco 2009). Yet many maintain that cosmopolitanism and nationalism are still antithetical, largely due to the exclusive imaginary inherent in nationalist discourses, but that more local attachments can work to undermine nationalist belonging by creating “a critical space of local care across difference” (Wise 2009).

The most recent theories of cosmopolitanism come under the rubric of “cultural cosmopolitanism,” broadly defined as an openness to and willingness to engage with cultural Others. Emergent theories encompass what Clifford (1992) described as “discrepant” cosmopolitanisms, most maintaining that cosmopolitans may retain local, particularized, and even nationalist identities and attachments. Some, such as Werbner, deliberately rescue the conceptual framework from elitist discourse – Werbner (2008) uses the phrase “demotic cosmopolitanism” in order to directly oppose the notion of it being purely elitist. Beck goes so far as to claim that “there is no cosmopolitanism without localism” (1998), rejecting the earlier elitist distinctions made by

Hannerz (1990) between the cosmopolitans and the locals, where cosmopolitanism was painted as essentially the “class consciousness of the frequent traveller” (or the domain of the white, male, middle class).

Beck has generated a significant oeuvre on cosmopolitanism, in which he argues that it is a process of “internal globalization” that creates what he calls “cosmopolitanization,” the third of five stages in the social sciences’ treatment of globalization (2009). When he first proposed his theory of “cosmopolitanization,” Beck argued that nationalist thinking presupposes a monologic imagination, whereas cosmopolitan thinking is dialogic. That is, the cosmopolitan perspective is “an imagination of alternative ways of life and rationalities, which include the otherness of the other” (1998); it is “thinking and living in terms of *inclusive oppositions*.” He goes on to argue for the social sciences to move on from “methodological nationalism” to “methodological cosmopolitanism,” which will replace “the currently prevailing ontology and imaginary of the nation-state” (2009, p. xii).

Beck claims that the collection *Cosmopolitanism in Practice* (Nowicka and Rovisco 2009) “introduces a fifth phase, namely the question of what does cosmopolitanism in practice mean” (Nowicka and Rovisco 2009). He and the other contributors to that volume attempt to move beyond merely “prescriptive” or “descriptive” conceptions of cosmopolitanism and to “illustrate some of the ways in which cosmopolitanism can be used as an analytical tool to explain certain identity outlooks and ethico-political practices that are discernible in a variety of social and institutional settings” (Nowicka and Rovisco 2009). It is this fifth stage to which culinary cosmopolitanism belongs, identifying cultural and cosmopolitan identities and practices through everyday engagements with multicultural foodways.

Unravelling Food Adventuring from Culinary Cosmopolitanism

A risk in any study of cosmopolitanism is to mistake discourses of cultural adventuring,

something seen frequently in culinary realms, for openness to and willingness to engage with cultural Others. In Ghassan Hage’s view, “Anglo-” (shorthand for “Anglo-Celtic” or “Anglo-Australian,” i.e., “white” in Australia) enrichment discourses create a sort of “multiculturalism without the migrants,” which “conceives of ethnicity largely as an object of consumption” (1997). In this same vein, bell hooks has famously argued “...within commodity culture, ethnicity becomes spice, seasoning that can liven up the dull dish that is mainstream culture” (1993).

In Bourdieu’s seminal work on social stratification and “taste,” he gave us terminology such as cultural, social, and symbolic capital and the concepts of *habitus* and *fields* (1979). Bourdieu’s sociological study from the late 1970s argued that a person’s cultural and social capital will be almost exclusively determined by inheritance, that is, by the class and situation into which one is born, with some effect from education. Hage (1997) makes a Bourdieuan argument that people not only consistently accrue cultural capital as they maintain their social distinctions, but that this does symbolic violence to ethnic Others in making them invisible or existing only insofar as they can “perform” their authentic ethnic selves for elite Others (usually Anglo in Hage’s work in Sydney).

Hage argues via Heidegger that the discourse of value “places the dominant culture in a more important position than other migrant cultures” and that “while the dominant White culture merely and unquestionably *exists*, migrant cultures exist *for* the latter” (1998). In his discussion of the “White multiculturalist fantasy,” Hage claims that in positioning migrant cultures as “exhibitions” in a sort of “multicultural fair” and Whites as the tourists “being enriched,” the Whites have “blocked” the “reality of the ethnic eater” (1998).

On the one hand, this particular discourse is indicative of Anglo hegemony through discursively valuing Others’ foods that “enrich” their lives. On the other hand, if one looks back to the history of most migrant restaurants, it is clear that the “ethnic eaters” were there first, and in many or most cases of such eateries, they remain present in significant numbers. In truth, many habitués of multicultural restaurants seek out those

establishments that have a visible presence of “ethnic eaters” as a sign of “authenticity” and therefore, presumably, a higher quality (more pleasurable) dining experience (and, of course, a sign of their own distinction (Bourdieu 1979) as cosmopolitans possessing considerable knowledge of the Other).

Hage himself acknowledges this, claiming that “Cosmo-multiculturalism expresses a clear liking for ethnic cultural products that appear to exist in and for themselves. The experience is one of entering a restaurant that is not aiming to satisfy western needs but an ethnic clientele” (1997). Here Hage is contradictory on a number of points. First, if “cosmo-multiculturalists” have “blocked the reality of the ethnic eater,” how can they be seeking verification of authenticity in the presence of the same? Second, according to Hage, the ethnic provider of food is interpellated as a powerless object of the nation if the cosmo-multiculturalist centers his discourse around eating, rather than focusing on the production and “gift” of the food. However, he argues that enjoying food that is (ostensibly at least) prepared not for the Anglo eater, but for a communal ethnic experience to which the Anglo feels privileged to partake as a sort of “trespasser,” is “perverse.” It’s unclear what option Hage leaves the (presumed Anglo) culinary cosmopolitan that won’t do symbolic violence to the migrant producer.

It is critical to the development of culinary cosmopolitanism to understand the ways in which all versions, Anglo or non, bourgeois or working class, and knowledge class or not, deploy cosmopolitanism as a way of making sense of a multicultural reality.

Heldke has written of the “culinary traveller” as someone “who moves into a cultural location other than one’s own, either temporarily or more long term” (2003). She includes travellers overseas, domestically, or even just to “ethnic” restaurants in one’s own town. Jennie Germann Molz, writing about culinary tourism in local Thai restaurants, argues that:

by participating in a food system, the culinary tourist is expressing and reinforcing his or her own identity while exploring the identity of the other that is represented by that food system. [...] As

Lucy Long suggests, while culinary tourism is “the intentional, exploratory participation in the foodways of an Other”, it often results in “teaching[ing] us more about ourselves than about the Other.” (1998, p. 185). (Molz 2007)

To illustrate an example of Hage’s “cosmo-multiculturalist” or Heldke’s “culinary traveller,” here’s a sample from a post on a Sydney food blog:

Sydney siders are well versed in all things Italian, if the number of pizzerias, trattorias and “Mama Mia’s” are anything to go by, but there’s always room for more eating, drinking and dancing in this town so “Viva Italiano,” I say. (Leong 2009)

Here, Leong’s celebration of “all things Italian” is exclusively Italian food – this is Hage’s “multiculturalism without the migrants.” And yet, importantly, does the reader know whether Leong in fact *only* celebrates “Italianness” for what it offers her in social distinction? Or does one also gain a better understanding of and therefore greater openness to Other cultures through their interest in the foodways of those cultures, even if that wasn’t the initial goal? Can elitist practices of food adventuring be a mechanism that enables more cosmopolitan attitudes?

Hage’s “cosmo-multiculturalism” has also been called “cosmopolitan capitalism,” which Leong (2009) has critiqued as a “glossy magazine” version of cosmopolitanism – like Hage, Littler views this as an elite lifestyle choice usually defined by habits of conspicuous consumption. Corpus Ong (2009), in his work on globalized media practice, cynically labels it “instrumental cosmopolitanism.” In each of these arguments, the people in question would fit into Hannerz’s (1990) opposition of “cosmopolitans” to “locals,” where he went so far as to claim that transnational migrants were not “real” cosmopolitans as they so frequently have little choice in the migration (economic or humanitarian refugees, essentially) and only engage with the “host” culture in the manner of tourists, which is to say, a very shallow engagement.

In Bell and Valentine’s (1997) chapter on food consumption in communities, the authors define cosmopolitanism as involving “the cultivating of ‘globalised cultural capital’ as a form of lifestyle

shopping which, crucially, involves possessing considerable knowledge about the ‘exotic’ [or] ‘the authentic’” which they point out is often referred to as a “colonisation or an intellectualisation of popular culture.” Kothari and Pearson (2007) mull over the same concern, using the terms “boutique multiculturalism” and “culinary cosmopolitanism” to worry about the elitist and colonizing tendencies of such systems of valuing. However, they point to a more hopeful conclusion when they comment that “While the mainstream may seek to fashion itself as more interesting and cosmopolitan by eating ethnic food, this type of consumption can also signal an important openness to cultural difference.”

While it is easy to see the Bourdieuan distinction of the knowledgeable cosmopolitan above, arguments such as Hage’s or Bell and Valentine’s leave cosmopolitanism in a rather cynical and sad theoretical space, leaving the ethnic Other little potential for agency and in fact seeming to contribute to the silencing of the migrant voice. Such a version seems to be critical of “possession of considerable knowledge” of the Other, which is surely in direct contradiction to ideas of belonging, in which being able to make meaning is essential (Williams 1961). It seems that what Hage is really criticizing is the cavalier attitude of those who are distinguished by their knowledge of the exotic, which is closely tied to Heidegger’s discourse of valuing, rather than Raymond Williams’ discussion of making meaning and belonging. In this case, it is perhaps more useful to interrogate individual, everyday attitudes rather than making sweeping generalizations. It is important to work with and against the potential contradictions inherent in the acquisition of cultural capital in order to understand what cosmopolitanism is and what benefits it can offer a multicultural society.

Rescuing “culinary cosmopolitanism” from its more recent elitist connotations by taking it back to its philosophical roots offers a way forward to understanding the importance of engagement with multicultural foodways in the development of cosmopolitan subjects.

Generally speaking, those who maintain that Hage’s “cosmo-multiculturalists” are not

“genuine” cosmopolitans are typically writing about elite Anglo populations, and much of the most contemporary theory around “banal” or “vernacular” cosmopolitanisms has focused on transnational migrant groups who are typically not of Anglo descent. Some of the most interesting work in this newer field comes from non-metropolitan or “southern” academics and seeks to decenter the metropolitan, elite, white discourses in order to demonstrate instances of cosmopolitanisms all over the world (Werbner 2008; Nowicka and Rovisco 2009).

“Hopeful Intercultural Encounters” and Culinary Cosmopolitanism

In Amanda Wise’s (2009) ethnography in the Sydney suburb of Ashfield, she argues that where she found “hopeful intercultural encounters,” a common element was:

certain forms of manners, recognition, gratitude and hospitality, which have the capacity to facilitate the development over time of forms of interethnic belonging, security and trust. Such interethnic social capital, as I term it, is an essential prerequisite for the creation of dispositions of the open, joyful and hopeful kind, full of possibilities for opening up to otherness.

Food and eating, which “are central to our subjectivity, or sense of self, and our experience of embodiment,” (Lupton 1996) are therefore central to opportunities in which it is possible to develop “interethnic social capital.” Not only is food an everyday visceral aspect of life, involving taste, emotion, and memory, it is a site of frequent exchange, whether as a commodity, a gift, or an act of nurturing. As Duruz puts it, “‘eating together differently’ [...] has become a recognition of the (here, mildly) disruptive politics of exchange – of food, of histories, of memories – at the table of global–local belonging” (2006). It is critical to the project of culinary cosmopolitanism, then, to understand just what does happen at the “glocal” table and to identify the points in the continuum of shopping/growing, preparing, feeding, and eating that offer the most enabling spaces for cosmopolitan praxis.

Summary

Culinary cosmopolitanism is part of a long history of people's attempt to be open to and engage with cultural Others. Through practices of production and consumption of food and foodways, people of all classes and ethnicities seek to understand and belong to a global community, often through very local attachments, and critically, over the table.

Culinary Tourism

Lucy M. Long
Center for Food and Culture, Bowling Green,
OH, USA

Synonyms

[Cultural tourism](#); [Food tourism](#); [Gastronomic tourism](#); [Sustainable tourism](#)

Introduction

Culinary tourism is the focus on food as an attraction for exploration and a destination for tourism. Although food has always been a part of hospitality services for tourists, it was not emphasized by the tourism industry until the late 1990s. It now includes a variety of formats and products – culinary trails, cooking classes, restaurants, farm weekends, cookbooks, food guides, and new or adapted recipes, dishes, and even ingredients. While most culinary tourism focuses on the experience of dining and tasting of new foods as a

commercial enterprise, it is also an educational initiative channeling curiosity about food into learning through it about the culture of a particular cuisine, the people involved in producing and preparing it, the food system enabling access to those foods, and the potential contribution of tourists to sustainability.

Culinary tourism involves numerous issues; many that accompany tourism in general as well as some that are specific to food. Because of culinary tourism's economic potential as well as its role in spreading and shaping food cultures, the ethics attached to it are very real concerns. It is a significant force in globalization and offers rich possibilities for intercultural communication and understanding. It is essential then that both scholars and practitioners recognize its complexity and potential. This entry offers an overview of issues connected to culinary tourism and some of the solutions that have been suggested for dealing with them. It also addresses competing definitions of culinary tourism as a field of study, since different approaches focus on different issues.

Issues: Definitions

Tourism based on food is known by several terms, and these terms reflect different approaches to it as a field of study as well as an industry niche. Perhaps the first was "gastronomic tourism," suggested by cultural geographer Wilbur Zelinsky in 1985 in an analysis of ethnicities prevalent in restaurants in the United States. Similarly, Bell and Valentine used "kitchen table tourism" in 1997 to address the virtual exploration of other food cultures through modern technologies. "Culinary tourism" was introduced in 1996 by folklorist Lucy Long as a humanities perspective on the meanings and implications of eating out of curiosity and was later refined to "the intentional, exploratory participation in the foodways of an other; participation including the consumption, preparation, and presentation of a food item, cuisine, meal system, or eating style considered to belong to a culinary system not one's own" (2004: 21). Culinary tourism from this perspective is a negotiation of exotic and familiar, with otherness

depending not only on an individual's or group's experiences but also including domains such as region, class, gender, religion or ethos, age, along with ethnicity or nationality of a food. It also includes all the activities and practices associated with food consumption.

Long's edited volume, *Culinary Tourism* (2004), helped establish the phrase in both the humanities and the tourism industry, where it was adapted by the American-based International Culinary Tourism Association for tourism that features unique and memorable dining experiences. This shift to professional and commercial interests around tourism raised issues common to the distinctions between applied and "academic" approaches to scholarship and tourism in general, particularly in the idea of knowledge being used to exploit resources and tourists to profit the tourism industry.

Meanwhile, scholars in tourism studies and other fields, notably anthropology, were also studying the phenomenon and using other terms. Tourism scholar C. Michael Hall defined "food tourism" in 1997 as tourism in which the prime motivation for the tourist was a "...desire to experience a particular type of food or the produce of a specific region." Hall and Sharples refined that definition to: "visitation to primary and secondary food producers, food festivals, restaurants and specific locations for which food tasting and/or experiencing the attribute of specialist food production regions are the primary motivating factor for travel" (2003). The extensive publications by Hall and his colleagues take cross-disciplinary approaches in examining motivations of tourists and the development, management, and marketing of food tourism products. They also recognize the potential impacts of tourism beyond the industry, encouraging a research-based model for ethical tourism.

"Gastronomic tourism" used in 2002 by Anne-Mette Hjalager and Greg Richards is similar to "food tourism" in involving travel to food but is also presented as an emerging discipline recognizing both gastronomy and tourism as dynamic cultural constructions reflecting specific histories and contemporary interests. Pricilla Boniface's term "tasting tourism" is similarly used to

understand the broader forces that have turned food and drink into tourism attractions (2003). She draws upon work in cultural studies to understand the nature of tourism in the modern world and how tourism can change the meanings of food. She also offers a framework for understanding the motivations of tourists, a significant issue within tourism studies.

Scholarship on culinary tourism has continued to grow so that it is now frequently discussed in journals and conferences in tourism studies as well as other disciplines, exploring the role of culinary tourism in identity construction, maintenance of cultural and culinary heritage, and defining cultural boundaries. Much of this scholarship also now emphasizes an understanding of how such tourism can be made sustainable and beneficial to all who are involved in it. This requires examining the impact of tourism on economies, environments, societies, and cultures of both the host communities and the tourists involved.

Issues: Economic

Tourism in general is a major global industry, expected to be worth \$10.8 trillion and provide 296.2 million jobs by 2018. Culinary tourism is a growing niche within the industry, estimated to becoming stronger as more providers and tourists become aware of it. Culinary tourists are thought to belong to higher income levels, able to spend more money on other hospitality services accompanying dining experiences (lodging, tours, etc.), and to be better educated and more culturally sensitive. This makes them a desirable clientele, and governments and policy makers see this type of tourism as a positive force for economic development. Along with providing employment opportunities, it also creates markets for particular foods and food events. Because of the current emphasis on locally sourced ingredients, it also supports local food producers and can be seen as a way to insure that the food system in general is intertwined with and supporting local economies – the “multiplier effect” in which businesses supplying and supporting the tourism industry benefit from tourism activities (Gmelch 2010; Chambers

2010). This would, in theory, include such things as the farmers who supply the restaurants feeding tourists or schools training students in hospitality management or culinary arts.

The economic benefits of culinary tourism seem clearly positive; unfortunately, it is never that simple. Tourism in general depends upon the spending of individuals from wealthier nations. This source can change due to weather, political events, natural disasters, and a host of other variables. Not only can host cultures’ economics become dangerously dependent on such unstable tourism monies, but local food systems (and social structures in general) may also adapt to accommodate tourists needs. Also, tourism is frequently controlled by companies outside a host community who their own suppliers and bringing in their own staff (Gmelch 2010; Chambers 2010). This results in economic “leakage,” with the money brought in by tourism leaving that community. Similarly, there is no guarantee that money made from culinary tourism is shared in equitable ways within the host community or used in ways that benefit the larger group. Furthermore, “branding,” which is seen as a way to successfully commodify and market a region, locale, culture, or group’s food, oftentimes focuses on one food or ingredient to the detriment of others, creating a monoculture, so to speak, again, an unreliable basis for an economy.

A particularly significant issue in culinary tourism is the possibility it has for “recoupling the food chain,” bringing producers and consumers closer together without the middle links of processing, packaging, distributing, and marketing of food. Since culinary tourism can make tourists more aware of the food they are eating, it can also turn their attention to where that food comes from and how it is grown. Tourists can then create a demand and a market for food that is produced sustainably and locally. This, in theory, puts more money in the pockets of producers, by focusing on locally produced foods. This then “recouples” the food chain, moving consumption closer to production.

In theory, culinary tourism focused on local producers is more likely to spread the money equitably through the community. One issue, however, is that standard culinary tourism focuses

on high-quality and memorable dining experiences. That means an emphasis on artisan production. Not all producers are able to fit those criteria, and not all foods will be attractive to tourists, so those producers are then left out of the tourist economy even though they may be necessary and integral to the local culture.

Culinary tourism is now being tied to economic development in a number of countries as well as in the United States. This is coming from governmental initiatives as well as the tourism industry itself. Some of the most interesting (and probably, most viable) are cooperatives of growers who band together and market their products along with their farms as tourism destinations. In this way, they ensure that they are all collaborating rather than competing with each other. They also then have more variety of products and activities to offer tourists, therefore attracting more tourists as well as giving them reasons to stay longer at their destination.

Within the tourism industry, ethical issues tend to boil down to a perceived need to balance competitiveness and sustainability. **Competitiveness** refers to the industry as a whole competing with other industries for markets and resources as well as individual businesses competing with each other within the tourism industry (and hospitality and travel industries).

Sustainability refers to the endurance of the resources used for tourism. This includes the physical resources (environment) as well as the economic ones. Tourists themselves are actually seen as a resource since businesses compete for them and ultimately depend on them for survival. Sustainable resources also include the local culture, traditional expressive forms that “add value” to a destination, and the social stability of the host community. The last is important since it translates into less crime, friendlier interactions between tourists and “natives,” and better trained workers for the service industries connected to tourism. A broader perspective on sustainability identifies four “pillars” needed to ensure the endurance of resources: economies, environments, societies, and cultures. Culinary tourism involves and can potentially contribute to each of these domains.

In practice, these two issues are frequently in conflict with each other: short-term monetary profits oftentimes take precedence over long-term endurance of resources, particular in areas in which the local economy is inequitable. Also, the costs (negative impacts) and benefits (positive impacts) differ according to each participant (stakeholder) – hosts (tourist destination culture and society), guests (the tourists), tourism providers (businesses), local governments, and the natural environment – in a particular tourism initiative, so that issues surrounding culinary tourism often have no single simple resolution. The World Tourism Association provided guidelines in 1996 defining sustainable tourism, and these are promoted, with varying success, for culinary tourism as well.

Issues: Environmental

Tourism in general can lead to depletion and degradation of environmental resources – land, water, air, flora, and fauna – when those resources are improperly or overused or if the amount of tourism activity exceeds the “carrying capacity” of a host community. Culinary tourism can have similar issues as well as ones specific to food if it promotes products that are threatened or unsustainably produced. (Travel to China for consumption of sharks fin soup would be an example.) Although some culinary tourists seek such “extreme eating” experiences or focus primarily on the aesthetic experience of food free of morality, many are aware of the environmental implications/impacts of their food choices.

Because culinary tourists, for the most part, want to experience food in its native habitat and sociocultural context, they offer an incentive to maintain those habitats. Also, they tend to want high-quality and artisan foods, both of which are frequently produced in sustainable ways – smaller farms, handmade rather than relying on technology, and possibly organically grown. They also tend to want to eat a variety of foods, which, in theory, can encourage protecting the biodiversity of an area. (Unfortunately, this last desire on the part of tourists often translates into importing

foods that are not native or locally grown.) As the industry continues to grow, though, more businesses and tourists are aware of the potential impacts it can have and are more willing to work within the guidelines of sustainability.

Because of the obvious connections between food and the environment, culinary tourism projects by 2010 frequently emphasize locally grown food produced with sustainable farming methods. This brings money to those growers and helps to establish them as viable links in the food chain. This in turn can have a positive impact on the environment since fewer resources tend to be used with fewer links. Culinary tourism is also combined with ecotourism, a niche that focuses on tourism practices beneficial to a local environment.

Issues: Social

Tourism in general, but including culinary tourism, is frequently critiqued as reflecting colonialist power structures that have historically created and maintained inequitable social systems (Gmelch 2010; Chambers 2010). It does create a class system based on “hosts” and “guests” in which guests are perceived as having more social and cultural if not economic status. This in itself can be problematic, especially since hospitality and friendliness can then become part of commercial transactions, leading to misinterpretations and interpersonal conflicts. Also, although the tourism industry oftentimes offers employment opportunities, except for a select few, these jobs tend to be low-paying and low-status in service industries in which workers have little say in their activities and must cater to the needs and whims of upper management and tourists. This can then breed social discontent and attitudes of resentment and distrust on the part of workers and does little to enhance cross-cultural experiences of tourists. Furthermore, jobs in tourism frequently are seasonal, so cannot be relied upon. The industry in general may also draw workers away from more stable, traditional, or socially significant jobs, disrupting traditional networks of exchange and impacting the community as a whole. Similarly,

culinary tourism can also be intrusive by bringing outsiders into private and domestic spaces, such as neighborhood markets, home kitchens, and in-group oriented dining establishments.

Simultaneously, culinary tourism can also offer opportunities that would never occur otherwise or for individuals who traditionally would not be given such possibilities. For example, domestic cooks may be able to now earn money by sharing their skills with tourists, perhaps elevating their own social and economic status. Similarly, tourist sites may change since some culinary tourists are now seeking out farms, markets, and small, family-run restaurants rather than the traditional tourist attractions. This can help to spread tourist dollars more equitably within a host community and allow for more socially sensitive interactions between hosts and guests. This might unfortunately be offset by the industry’s emphasis on “unique” and “memorable” dining experiences since they tend to feature high-class foods as well as those that are more exotic and rare, regardless of their actual place within the local food culture.

Culinary tourism can actually be seen as a positive force in some instances in which it brings attention to healthier ingredients and preparation styles and more sustainable production methods. Many tourists now seek out local and organic foods, actually creating a market for foods formerly ignored or supporting farmers who were struggling to compete in the more industrial agriculture-based global food system. Belize provides an example of culinary tourists shifting from the British-based cuisine of tinned and imported foods to locally grown, native fruits and vegetables. This can be interpreted as a positive change towards environmental and economic sustainability in the local food system.

Another social issue connected to tourism in general is its role in cross-cultural communication and understanding. It is hoped that by being exposed to another culture, individuals become more sensitive to that culture, more aware that members of that culture are fellow human beings so that tourism can be a way to understand other cultures and to resolve conflict. Food, in particular is perceived as a way to learn about and bond with

another culture. The simplistic assumption is that if people eat one another's food, they will better appreciate each other. Although food can be a window into another group's beliefs, histories, and practices, it is not an automatic bridge between different cultures or even different individuals. Too often, tourists focus on what is either exotic or tasty to them and fail to learn to appreciate the everyday foodways of a group. Also, "breaking bread" together is not always a pleasant or fruitful experience, but requires a deeper understanding of the food cultures of all participants as well as sensitivity to the social patterns connected to meals and food.

Issues: Cultural

The cultural issues surrounding culinary tourism are complex, partly because culture itself is complex, dynamic, and constantly being reconstructed and reproduced according to the interests and resources of individuals but also because so much of culture is intangible and interpretive, dependent on the perspective of the individual. This also means that the cultural impacts of tourism cannot be assessed quantitatively or conclusively. Because food has "material presence," it offers a way to explore many of these issues. It is helpful, though, to think of cultural issues in terms of both the conceptualizations around food and the actual practices of foodways.

Tourism in general tends to exoticize or "other" a group of people, commoditize their culture, and shape their traditions in a variety of ways that then make them more attractive to tourists. As a force of globalization, it can also speed up the processes of modernization and industrialization, homogenize and "sanitize" the host culture, weaken cultural identities, and spread an invented "tourist culture" lacking historical authenticity. At the same time (Gmelch 2010; Chambers 2010), it can also create markets for cultural practices; bring attention, recognition, and affirmation to cultural groups and traditions; and create opportunities for cross-cultural interactions and understanding. One of the issues, then, is whether tourism is qualitatively different from any other

exchanges between cultures. Critics point out that the difference in economic, political, and cultural status gives the tourist power to shape the public identity and image of the host culture in any way that suits them (Heldke 2003, 2005), and it is this imbalance of power that is the problem that means that tourism "colonizes" other cultures. The food cultures of both hosts and guests are then changed because of that colonization.

To "other" a group of people means to set them apart from oneself and to focus on their differences rather than their commonalities. This then allows tourism to treat individuals and cultures as "resources" rather than human. A popular phrase used in tourism marketing and planning is "exotic but safe." Applied to culinary tourism, it means that the food needs to be presented as exotic or strange enough to make people curious but familiar enough that they feel safe trying it. Food then is manipulated to fit those expectations, oftentimes changing it in some way or highlighting a food in a way not usually done within that culture or giving it new meanings.

This leads to issues of authenticity, another problematic concept connoting continuity with a culture's past, core values, or expressive forms. On one hand, culinary tourism often emphasizes foods and foodways experiences thought to be "authentic," that is, historically representative of a locale, but this emphasis can also ignore the dynamic quality of food cultures to change over time. Certain ingredients, recipes, or preparation methods then become canonized as the only accurate representatives of that culture, and the cuisine becomes "crystallized" into that form. Culinary tourism also may encourage "inauthentic" representations of the food culture by paying attention to foods perceived as the most unique, exotic, and interesting, requiring specialized culinary skill, high quality, and memorable. This in turn can create a "tourist cuisine" shaped to meet tourists' expectations.

Culinary tourism also commodifies food and foodways. While food is oftentimes the center of monetary exchange, tourist activities emphasize the value of a food to attract tourist dollars. This then trivializes and "trinketizes" cultural practices and forms, turning them into "playthings" and

souvenirs for tourists. Apart from being demeaning to the host culture, this process potentially weakens the emotional and social associations they carry, causing them to shift away from expressing cultural histories, identities, and beliefs. The luau in Hawaii, for example, has become a tourist production with stereotypical foods, shifting from the sacred meanings held within the community to simply a party and feast for the tourists (O'Connor 2008). Such impacts can ultimately weaken cultural identity.

At the same time, commodification, and tourism in general, may affirm those cultural identities and meanings. As outsiders, tourists often notice regional and cultural boundaries as well as distinctive practices. This attention can have positive impacts in defining and strengthening the identities behind those practices and can even shift the place of those identities in public consciousness to a higher status (Long 2010). Tourists may also provide financial and social support that enables participation in local culinary traditions.

This challenges the critique of tourism as homogenizing host cultures, making them all the same in order to please tourists. Some researchers argue, though, that culinary tourism actually discourages homogenization since it features foodways distinctive to specific locales, encouraging hosts to maintain or revive those local traditions (Meethan 2001; Wilk 2006). Culinary tourism can also encourage "glocalization," the adaptation of global products to local forms (Ritzer 1993).

Food being a commodity also changes the relationship between the producer–host and consumer–guest. It is not just a matter of good hospitality to offer food that one's guests will like; it is also good business. Recipes may be changed, ingredients substituted, and new foods invented to attract tourists. Also, festive dishes and meals tend to be featured rather than everyday foods, misrepresenting the food culture as a whole.

Culinary tourism raises questions of intellectual property rights connected to intangible cultural heritage. Can the recipes, preparation methods, or cooking styles of a culture be used by anyone who wants to for profit? Do members of that culture have legal ownership of those traditions, so that only they can claim them as

representing their culture? Furthermore, who within a cultural group has the right to define what is a tradition or a characteristic of the culture? Similar questions can be asked of entire cuisines and are being addressed in attempts to protect heritage from modernization and globalization. Geographical indicators are used in many countries to designate the accurate origin of a food product, with France establishing the Appellation d' Origine Contrôlée in the early 1900s to protect cheeses and wines. This is based on the older concept of *terroir* (taste of place) and allows regions to claim certain types of produce as belonging to them. An arm of the government also sets standards by which any produce from a designated region can carry an AOC stamp of approval.

Summary

Culinary tourism has significant impacts on food cultures, food systems, and the economies, environments, societies, and cultures surrounding them. These impacts are potentially beneficial but can simultaneously be harmful, depending on the perspective of the evaluator. It is essential that the complexity of culinary tourism be recognized so that issues can be addressed.

Dairy Ethics

Julia Lapp

Department of Health Promotion and Physical Education, Ithaca College, Ithaca, NY, USA

Synonyms

Dairy production; Farm animal welfare; Milk production; Milk products

Introduction

The English word “dairy” is derived from the Old English *daege* “kneader of bread” and middle English *deierie* “place for treating milk,” and *daye* “female servant” (Hoad 1996). According to Merriam -Webster’s Concise Dictionary, the term “dairy” is defined as “a farm that produces milk, a place where milk is kept and butter or cheese is made” or “a company that sells milk and foods made from milk (such as butter and cheese).” Hence, the term has mixed connotations of location for production of milk and milk products, as well as emphasizing the primary role that women historically played in dairy work as “dairy maids,” cheese and butter makers (Valenze 2011). The contemporary use of the word generally does not include human milk but is limited to milk produced by *Artiodactyla* order, mostly *Bovidae*

family animals (goats, sheep, cows, buffalo, yaks) that are produced for consumption by humans.

Ethics of dairy pertains to ethical considerations in the production of milk products and the methods of production employed. The primary ethical considerations related to dairy are related to animal welfare, use of hormones and medications in milk producing cows, pollution and greenhouse gas production, as well as practices of corporate farming and the disappearance of small dairy farms. Additionally, some nutritionists have questioned the recommended emphasis on milk consumption by the Dietary Guidelines for Americans and the American food guides (i.e., Food Guide Pyramid, MyPlate) as Eurocentric, given that populations of non-European descent are less likely to be able to digest the milk sugar *lactose*.

Background Humans and Milk Consumption

The most suitable first food for any newborn mammal is the milk of its mother (Williams and Worthington-Roberts 1992). Young mammals require a nutrient rich diet, and milk of lactating mothers has evolved to meet the specific nutritional needs of their offspring. In normal development, breast milk provides the sole source of nutrition to the young animal until it is able to consume other foods. Each mammal’s milk

provides an array of micronutrients, fats, proteins, and carbohydrates in proportions matching the needs of the nursing young to provide energy, promote growth, and development. Breast milk also provides species specific immune components, *immunoglobulins*, that lend protection while the new immune system develops. *Lactose* is the primary carbohydrate source found to varying amounts in all mammal milks. It is a disaccharide sugar made of two monosaccharides – *galactose* and *glucose* – bonded together.

The small intestinal tissue of young, nursing mammals (including humans) produces the enzyme *lactase*, which hydrolyzes or cleaves the bonds between *galactose* and *glucose*, thereby “digesting” it and making the two monosaccharide sugars absorbable and available for energy metabolism. In the normal course of development, genetic expression for lactase production only persists for the first few months of life while nourishment comes primarily from mother’s milk. Once the young animal is weaned, and it will never naturally consume milk again, lactase expression stops. This means that, in adulthood, the majority of mammals cannot effectively digest lactose, making milk an impracticable food source. This is also true for the majority of humans, who typically lose the ability to digest milk between the ages of 2–10 years and become lactose intolerant. An estimated 65 % of the human population, particularly those of Asian, Middle Eastern, Native American and First Nations, Aboriginal, and West African descent, have difficulty digesting milk for this reason (Ingram et al. 2009).

Humans are the only mammals that consume the milk of other animals. Paleoarchaeologists estimate that milk from other mammals has been consumed by humans for several thousand years, primarily following the domestication of mammals of the *Bovidae* family by formerly hunter/gatherer societies, giving rise to early pastoralism and agrarianism (Check 2007). Consumption of milk products by lactose intolerant adults requires processing of the milk to hydrolyze the lactose disaccharide, which is done via the introduction of lactose fermenting bacteria to produce foods like kefir, yogurt, and cheese. Archaeological

evidence in the form of perforated pottery shards, the oldest coming from a site in Poland, suggests that humans began these fermentation practices as long ago as 7000 years (Callaway 2012). The consumption of these fermented products provided adaptive advantages to pastoralists by allowing adults to consume the nutrient rich milk, while the lactofermentation also prevented spoilage of the milk by other bacteria. Archaeologists and geneticists speculate that, over time, some adults developed variations of the genes that play a role in lactase production (alleles) that perpetuated their expression (lactase persistence). This enhanced the ability to digest fermented milk products and allowed these adults to also digest unfermented milk. This genetic variation allowed these individuals to make use of milk as a valuable source of nutrition, particularly as a hedge against potentially devastating crop failures. Raising livestock for milk (and meat) presented a sustained and ready source of food and an adaptive advantage over hunting and gathering, which may explain the rapid spread of agriculture and pastoralism across the Euroasian continent. Of all ethnic populations, individuals of European heritage have the highest prevalence of genetic lactase persistence, approximately 80 %.

Over the centuries, milk from *Artiodactyla*, most often *Bovidae* family animals, has played a role in the development of many pastoral and agrarian societies of the Eurasian and African continents. Dairy foods, primarily fermented, were a dietary staple of the Ancient Greeks, Egyptians, Romans, Arabians (Bactrian camels), and many pastoralist tribal societies throughout Central Asia, Europe, and the Middle East, whose herding lifestyle was an adaptive strategy for life on the grasslands or the mountainous regions of Northern Asia (i.e., Tibetan Yak herding, Reindeer herding societies of northern Europe, Russia, and China) (Valenze 2011). Pastoralist societies have also existed for at least 3000 years in Eastern and Southern regions of Africa, where cows and goats were primarily herded.

Today, approximately 150 million households globally are engaged in milk production (UN FAO 2016). Global milk production is measured in energy corrected milk units (ECM), which

assesses total pounds of milk as well as energy (calories) provided from milk fat and protein (IFCN 2016). This calculation allows for temporal and geographic comparisons of livestock health, productivity, and energy values of milk. Currently, India is the global leader in total ECM production with 137.5 million tons ECM, or 16 % of the world total, coming from cow and buffalo milk (UN FAO 2016). Among nations that only include cow's milk in their total national product, the United States is the leader with 84.3 million tons ECM, followed by Pakistan, China, Brazil, and Germany (USDA 2016). The top dairy producing states in the USA are California, Wisconsin, Idaho, and New York.

This entry provides an overview of ethical considerations in dairy production, with a focus on contemporary practices of cow's milk production, which is produced globally in the largest volume.

Contemporary Dairy Production

Over the past several decades, agriculture in most parts of the world has undergone significant transformation from small, diversified farms to large, single product operations. This is true for dairy farms as well. There has been a shift away from small dairy farms to large, animal feeding operations (AFOs) where milking cows are “kept and raised in confined situations” (USDA 2016) of single-species, open-air barns, rather than grazing on pasture land (MacDonald and McBride 2009). Today, most of the world's cow milk comes from animal feeding operation (AFO) and concentrated animal feeding operation (CAFO) farms (Gurian-Sherman 2008), which are defined as animal feeding operations having more than 700 dairy cows on site (USDA 2016). These large farms comprise only a fraction of US dairies. Yet, their high production has resulted in more than 50 % of US milk coming from only 3 % of dairies. In 2012, California produced approximately 21 % of the annual US milk supply from 1650 dairies. California has the highest number of AFOs and CAFOs in the nation, with an average of 1782 cows per farm (CDFS 2015). New York, the fourth highest dairy producing state in the USA, has many more,

smaller dairies – 5,150 farms with an average of 610 cows per farm – that produce 6.6 % of US milk.

Global milk production has increased by more than 50 % since the 1980s (UN FAO 2016), and consumption of dairy products is increasing rapidly, particularly in emerging economy countries such as China and India. In wealthier nations, this increase is primarily due to increased milk productivity per cow, resulting from technological and feeding developments. In poorer countries that lack the technological resources, enhanced production is due to increased number of cows per farm and a move toward AFO and CAFO models of production.

Ethical Questions Inherent to Dairy Production

Probably the four primary ethical considerations related to dairy are ones that are implicit to the practice of one species (humans) harvesting the milk (or other products) from another species. The primary and foundational ethical issues, mostly embraced via the vegan and animal liberation movements, are those of “speciesism” (Singer 2009), “(the assumption) of superior status over those who are not members of our [human] species” (p. 572), and the concepts of “animal slavery” (Spiegel 1997) and commodification, both of which entail human exploitation of other animal species to their detriment or demise. The argument dictates that no matter how humanely the animal is treated, if it is raised for the purpose of providing foodstuffs for humans, an ethical issue arises.

The remaining considerations are tied specifically to dairy production. The first being that, regardless of production scale or means of impregnation, animals must be in a postpregnancy phase to induce lactation. This means that offspring must be produced that most often are then used for meat (i.e., veal, lamb) industries. For this reason, veal is a by-product of the dairy industry, as is beef that is rendered via the slaughter of dairy cows that no longer produce adequate milk. The US Department of Agriculture Food Safety and

Inspection Service (USDA -FSIS) defines veal as the meat from a calf that is raised until 16–18 weeks of age and weighing up to 450 lb. Some types of veal are produced from calves that are slaughtered at ages younger than three weeks. To produce pale, tender meat with a mild flavor, veal producers confine the calves to restrict movement and provide an iron poor diet. According to United States Department of Agriculture data (USDA 2016), the top 10 veal producing nations (including 27 countries of the European Union) slaughtered 14,417,000 calves in 2014. The use of nonproductive dairy cows for meat and the production of veal as a by-product of dairy present ethical dilemmas for lacto vegetarians. Second, milk produced by lactating animals is diverted away from their offspring to be consumed by humans instead as one or more forms of dairy product. This deprives young animals of a primary nutrition source that is produced in direct response to their birth and can result in stress for both the calf and cow (Flower and Weary 2001). Third, in order to continue production of milk, dairy animals must be impregnated at least every year which, in combination with enhanced lactation, can stress the animal's body and contribute to lower life expectancy (Oltenacu and Broom 2010).

Animal Welfare

Milk Productivity and Health of Dairy Cows

In addition to those ethical considerations described above, there are other practices of the dairy industry that pose risk to the welfare of dairy animals. Milk yield per cow has more than doubled over the past five decades (MacDonald and McBride 2009). These increases are largely the result of dietary formulations, genetic selection and breeding, and the use of recombinant bovine somatotropin (rBST), which is an injected hormone produced via genetic engineering that compounds the effects of endogenous hormone to enhance milk production. The United States Food and Drug Administration first approved rBST for use in animals in 1993 under the trade name "Posilac," with Monsanto Corporation holding the patent. Since that time, there have

been multiple clinical trials to assess the safety of rBST in both dairy cows and humans. Generally, studies show preliminary evidence of possible increased health risks to humans, but acknowledge the difficulty in assessing such risks, and demonstrate statistically significant risks to dairy cows (Raymond et al 2010; Nachman and Smith 2015).

Regardless of the cause, increased annual milk productivity is associated with decreased lifespan of dairy cows (Oltenacu and Broom 2010). An accepted explanation for this association is the resource allocation theory (RAT) that asserts that animals bred for high productivity in one metabolic function (i.e., milk production) are likely to experience compromise in other behavioral and metabolic functions such as fertility, immune function, and tissue healing and repair. Dairy cows bred to be highly productive are at a higher risk for several pathologies. Two of the most problematic are lameness and mastitis, which are considered to be significant welfare and productivity related concerns.

Lameness occurrence varies with animal management practices but has been estimated to occur in more than 50 % of animals on many farms (Warnick et al. 2001). Lameness results from a variety of conditions of the foot or leg including bruising, sole ulcers, abscesses, sores and cuts, injuries related to moist, improper hoof trimming, slippery or poor quality flooring, poor nutrition, or injury incurred in animals that are stressed or rushed when walking (i.e., moving cows from paddock to barn). Use of rBST has been shown to be associated with up to an estimated 55 % increased risk of lameness (Dohoo et al. 2003). Lameness also contributes to significant decreases in milk production, particularly if due to infection or ulceration, and it is a frequent cause of unintentional culling of animals when treatment costs outweigh productivity (Warnick et al. 2001).

Mastitis is an inflammation of the mammary gland, usually caused by infection, that if left untreated can result in death of the animal (Merck 2015). Many mastitis causing bacteria can be spread among cows from unclean hands of workers, contaminated milking machines, or bedding used for cattle. A 2003 Canadian

Veterinary Medicine Association/Health Canada meta-analysis comparing rBST herds with those not exposed found a 25 % higher risk of mastitis with rBST treatment (Dohoo et al. 2003).

Environmental Concerns

The second area of concern related to production of dairy is with regard to environmental impact. The rise of dairy consumption since the 1980s (particularly dairy products other than milk, such as cheese), and related increased production in many countries, has contributed to the burden of greenhouse gas (GHG) production, particularly methane (CH₄) from manure and flatulent cows (United States Environmental Protection Agency, 2016). According to the Intergovernmental Panel on Climate Change (IPCC), methane is the second most prevalent of the GHG produced, comprising 8.7 % of total GHG emissions, yet with a capacity to trap (global warming potentials – GWP) heat in the atmosphere of 21 times that of carbon dioxide. Methane from enteric fermentation (from ruminant animals) is considered to be a leading producer of methane gas.

Additionally, accumulated manure piles can contribute to pollution of natural waterways and aquifers with nitrates, phosphorous, *E. coli*, and coliforms, which have been documented problems in some dairy communities (Guerian-Sherman 2008). Air quality and physical effects on humans – such as respiratory issues or migraines – have also been documented.

Human Health

In addition to the above environmental concerns, and related risks posed to human health, the primary health concerns linked to dairy include the question of lactose intolerance, overt allergies to the milk protein casein, and cardiovascular disease risk linked with saturated fat found in dairy products. However, in recent years, additional concerns have been raised. The effects of rBGH and resulting higher circulating levels of insulin-like growth factor (IGF-1) among milk

drinkers has long been a concern for the potential carcinogenicity of dairy consumption (Nachman and Smith 2015). Recent studies have found positive correlations between higher intakes of dairy foods and increased risk of certain types of cancer, such as prostate and ovarian, and evidence of a protective effect of dairy consumption against colorectal cancer (Amiri et al. 2015). Lactose and its metabolites are believed to play a role in ovarian and prostate cell mutation, while the vitamin D and calcium found in milk are thought to possibly play a role in protection against colorectal cancer. However, causational mechanisms have not been established and questions also remain as to whether these potential concerns outweigh the human health benefits of milk consumption.

Conclusion

Humans have been consuming milk from other *Bovidae* mammals for thousands of years. Ethical considerations stem from foundational ones of exploitation of one animal species for use by another to animal welfare concerns related to contemporary dairying practices such as animal feeding operations and efforts to increase dairy animal (primarily cows) productivity. Environmental and human health effects of dairy production also present ethical concerns as global dairy consumption continues to increase.

Introduction

Dairy production, particularly in the USA, has been an amazing success story of utilizing increased understanding of cow biology and advanced technology to transform the average cow of a hundred years ago producing 5 kg/day to one producing about 30 kg/day today (Capper et al. 2009). Along with that tremendous increase in production, however, have come increased concerns about the ethics of dairy production as it relates to animal rights, welfare, and duties, environmental issues, allocation of scarce resources, and issues surrounding the technology and science used to advance dairy production (see “► [Animal Welfare in the Context of Animal Production](#)”; “► [Climate Change, Ethics, and Food Production](#)”; “► [Environmental Ethics](#)”). Vegetarianism in the USA has been at about 5 % for the last 10–15 years, with the amount of vegans being closer to 2 %. This leads to the assumption that the vast majority of Americans consume dairy products (some may not consume dairy products and not be vegetarians or vegans). For this reason, ethical issues regarding animal welfare and impacts on resources and environment will be focused on, rather than the use of dairy products. These are not only farmer, scientist, or business issues but also and possibly more so consumer issues. It is up to the consumer to become educated about the issue and decide what they are willing to accept.

General Practice

Dairy cows are usually required to produce a calf about once a year, or they are removed from the herd. Most dairy cows are impregnated via artificial insemination (AI). Increases in milk yield from improved genetics generally do not warrant keeping a cow beyond three to four lactations. Approximately 33 % of the eight million cows in the USA are slaughtered every year with the average age of the cow being culled at between 5 and 6 years old (see “► [Industrialized Slaughter and Animal Welfare](#)”). A similar cull rate and average age are reported in Canada (Government of Canada 2012). A cow can live up to 15–20 years. Expert advice on nutrition, including forage management, reproduction, and general management, is needed when introducing cows of high genetic merit into a dairy herd. High metabolic turnover in such cows can mean that they have a greater risk of mastitis, lameness, failure to become pregnant or maintain pregnancy, and other metabolic disorders. Many consider keeping the dairy cow pregnant most of her life (or any production of animal for that matter) to be an ethical issue (see “► [Corporate Farms](#)”).

Traditionally, producers generally aimed for a 305-day milking period once the calf is born (Fig. 1). Because of the high milk production of today's cows and their physiology, feed intake generally lags behind rising milk production.

Dairy Production: Ethical Issues, Fig. 1 Standard 365 dairy cow relative feed intake, milk production, and body weight. The parameters are not drawn to scale

A cow must be in good condition entering this phase, because she will lose weight. Once milk production starts to decline and feed intake exceeds requirement, the cow will regain weight. A 305-day milking period allows cows to regain condition before the birth of another calf after 365 days. New management techniques and strategies allow some producers to increase peak yield and persistency of yield, which allows the cow to be milked a longer time. Because of a number of reasons, many cows are not rebred within the 60-day period, so increasingly this regimen is not followed.

Metabolic Disorders of Dairy Cows

The few weeks just before calving and just after calving, known as the transition period, are the most stressful in terms of metabolism for the cow. Metabolic disorders most frequently identified in dairy cows include subacute and acute acidosis, laminitis, ketosis, displaced abomasum, liver abscesses, metritis, mastitis, milk fever, bloat, and downer cow. Twenty-five percent of cows that are culled from the herd do so within the first 65 days in milk, often as a result of one or more metabolic disorders. Many of these metabolic disorders are often the result of issues with management relating to nutrition during this period (see “► [Animal welfare in the Context of Animal Production](#)”). Maximum milk occurs with maximum grain. Cows do have a fiber requirement, however, and the fiber and grain intake must be optimized. One in two cows will develop at least one metabolic disorder while in the herd, and many metabolic disorders increase the incidence of another. To produce the high milk yields that modern dairy cows do, nutrition, reproduction, and health must all be balanced precisely.

If not balanced properly, the fragile system fails, and the cow develops a metabolic disorder. Some farmers are much better at managing and caring for the well-being of their animals than others. Bigger “factory” farms may have the resources to have cows checked (whether by human or technology) several times daily.

Small farms may have the ability to give a lot of attention to individual animals. The well-being of the animal rests largely in the hands of the farmer and his employees and their attitudes to their cows.

Lameness in their cows is a major welfare concern on many dairies. Lameness follows only mastitis in the number of cases each year. Most frequent causes of lameness are laminitis, claw disease, digital dermatitis, and foot rot (Bicalho 2011). Major economic losses occur, not only because of treatment costs but also decreases in dry matter intake resulting in lower milk yields, milk that must be disposed of, lower reproduction rates, and other health problems. Lameness is a leading cause of culling in many herds. Nutrition and feeding, housing, genetic influences, concurrent disease, injury, and environment all are contributing factors to incidence and severity of lameness. While cows on pasture may have a lower incidence of lameness, lameness still occurs. Incorrectly designed paddocks and trails to the milking parlor can lead to lameness. In addition, these cows must be moved indoors during the cold season (about 6 months in central NY), and barns must be free of situations that can cause harmful leg and feet injuries. Even parturition can cause lameness if a cow lays too long on one side. Lameness is undoubtedly painful. Causes for lameness must be quickly resolved. Here again, attitude of the farmer plays a major role in the incidence, severity and occurrence, regardless of herd size.

A downed cow arriving at the slaughter plant is a horrible site, and it is no longer legal for downed and downer cows to be transported to slaughter. The cow should be humanely euthanized. The occurrence of bovine spongiform encephalopathy (BSE; “mad cow disease”) prompted changes in legislation that not only prevented these animals from entering the food chain but also prevented these animals from being transported, something that had long been needed. There are numerous reasons that an animal can go down – metabolic disorder, injury, and problems during parturition. These animals must be treated quickly; due to their large size, permanent injury can occur if they remain on one side too long. They become

paralyzed (downer cow), and the only humane thing to do is to euthanize the cow.

Dairy Calves

When a dairy calf is born, it is usually removed from its dam very quickly. This procedure has drawn the ire of much of the public. The reality of the situation cannot be described by the picture that is formed in the mind, that of a calf and mother being torn apart. Modern dairy cows are not selected for their mothering abilities, so the instinct in them is not as strong as in beef cows (see “► [Beef Production: Ethical Issues](#)”). In addition, researchers have shown the maternal–calf bond takes time to develop. The earlier the calf is removed, the less trauma there is to the calf and dam. It is extremely important that the calf receive an adequate quantity of colostrum to insure adequate passive immunity, until the calf immune system develops on its own. Removing the calf at an early age makes sure this happens. Many *prima parous* cows do not produce the quality or quantity of colostrum necessary to insure the health of the calf. The calf is also removed from a potential unhealthy environment and can be easily cared for if sick or injured. The cow also can be treated if a metabolic disease resulting from calving occurs.

Dehorning is undoubtedly a painful process. After about two months of age, “part of the frontal sinus extends into the base of the horn. When the horn is removed at this stage, the sinus is exposed and increases the risk of infection. Horns in older calves usually have a large blood supply. Coagulants, clamps or tourniquets should be used to control bleeding, and insect control should be used to prevent flies from laying eggs in the exposed sinuses.” Dehorning should only be done under the supervision of a veterinarian and only done in extenuating circumstances. Anesthetics and analgesia should be used. Dehorning, however, is not technically what happens to dairy calves; a more appropriate term is disbudding. “Disbudding involves the removal of horn-producing cells in calves less than two months of age. At this stage, horn buds are still

free-floating and not yet attached to the frontal bone of the skull. Disbudding by caustic paste or hot-iron destroys horn-producing cells in the horn bud. Horn buds can also be physically excised using a knife or tube/cup/spoon. Disbudding is the preferred method of horn removal by the American Veterinary Medical Association, which also recommends the procedure be performed at the earliest age practicable” (Naylor 2015). Though much less painful than dehorning, analgesia and anesthetic use should be considered. Most dairy cattle are not polled (born without horns). Disbudding is done in concern of worker and cow safety.

Tail docking was a practice introduced in New Zealand and is seen as a procedure to enhance worker comfort and safety from disease. Tail docking was also seen as a way to increase hygiene in the cow, reducing incidence of mastitis and tail injuries. Much of the consuming public considers this practice inhumane, although many in the USA who support this view do not hold the same opinion of tail docking in dogs. Cows’ tails are used for fly control, so excellent fly control measures are needed for producers using this practice. Behaviorists also have shown tails to be important for communication. Researchers have not found scientific reasons to continue the practice. Tail docking is no longer common management in New Zealand. Denmark, Germany, Scotland, Sweden, and the UK, and some Australian territories prohibit docking tails as routine management. Tail docking is declining in other countries including the USA and Canada, although it remains common in some geographic regions. The American Veterinary Medical Association (AMVA) and the Canadian Veterinary Medical Association both oppose tail docking as a routine management practice. The American Association of Bovine Practitioners and the National Mastitis Council support the National Milk Producers Federation (NMPF) and Farmers Assuring Responsible Management (FARM) program guidelines which will discontinue the routine tail docking of cows effective January 2017. Many of the larger milk co-ops and companies have already adopted these guidelines, so it is likely that the practice will be all but discontinued

within a few years. The issue of tail docking is a very good example of the types of the ethical issues that will continue in the dairy industry. Consumers, many of them who are unaware of the reasons for tail docking, are driving change in the industry. Farmers are concerned that practices are changing farming practices, some of the practices which may not improve the welfare of the animals or the workers. Scientists, in the middle, use scientific techniques to determine answers to difficult issues, which may also require input from consumers and farmers.

Veal Calves

Some six million veal calves are produced in the European Union (EU) each year, and another 450,000 are produced in the USA. These calves, mostly males, are the by-product of the dairy industry, which has little need for male calves. Often, the cost of bringing these calves to market is more than producers get for the calves, sometimes resulting in an attitude that places little value on the lives of veal calves. Colostrum or antibiotics are not always fed to newborn male calves. Providing for the health of these male calves is both a welfare and an ethical issue and is certain to give the industry a black eye if not attended to (much like the down cow issue). Calves must receive the same treatment as female calves do until they leave the farm (see “► [Animal Welfare in the Context of Animal Production](#)”).

When the public is asked about veal calves, many probably picture a young animal lying in a small wooden crate, unable to turn around, many times unable to stand due to anemia, and covered in its own waste. This picture is largely untrue in developed countries today. *EU Calves Directive* has outlawed the use of crates like this since 2007; the directive “prohibits the use of confined individual pens after the age of eight weeks. The Directive, amongst other things, sets out minimum dimensions for individual pens and for calves kept in group. Calves are not to be tethered (except under very specific circumstances) and must be fed according to their

physiological needs. In particular their food must contain sufficient iron and a minimum daily ration and fiber food must be provided” (Council Directive 2008/119/EC of 18 December 2008). In the USA veal crates must be completely phased out by 2017. Eight states have already banned veal crate use and many of the larger buyers of veal do not permit the practice. Producers cannot feed animals a diet insufficient to meet the animals’ requirements and must start providing the calves some fiber by eight weeks of age.

Veal is soft pale meat obtained from young calves, with the calves generally fed for 4–5 months (American Veterinary Medical Association 2008; AVMA). Prior treatment of veal calves resulted in a white meat that was a high-value meat product to the restaurant trade. Today’s practices result in meat that is still soft, but pink instead of white. Studies have determined that there is no difference in taste or tenderness between the two veal types. Some consumers still prefer the white veal, however. Some education is still clearly needed.

Biotechnology efforts have resulted in procedures which can sex semen with increasing accuracy. This would result in mostly females being born or only male animals that were wanted for purposes such as artificial insemination (AI) bulls. Because most dairy cows are already artificially inseminated, this technology would not increase animal stress. Stress could decrease during parturition, as females are generally smaller than males. Dairy producers would no longer have unwanted animals they need to dispose of. On the other hand, veal producers would suffer a loss of income. In addition, biotechnological techniques developed for use with animals could be used with humans, which is a large ethical issue.

Recombinant Bovine Somatotropin

In November of 1993, the US Food and Drug Administration (FDA) approved the use of recombinant bovine somatotropin (rbST), one of the first agricultural biotechnology products to be so

approved. Approval set off a maelstrom of heated exchanges between the consuming public and science, government, and big business. Is rbST safe for cows and people? The debate continues. Before FDA approval, rbST was studied extensively in both scientific and field trials. Hundreds of trials have been run since FDA approval. The vast consensus of these studies is the properly managed use of rbST has no ill effects on cows or people (Collier and Bauman 2014). There are a few studies that have linked rbST to an increased incidence of mastitis and other metabolic disorders. There were reported increases in lameness and injection site issues as well. Other than injection site issues, which cannot be overlooked, increases in health issues may be more the result of the increased level of milk production and the increased management required than the use of rbST per se. As far as human health is concerned, there is little to no rbST that transfers into cows' milk, pasteurization would destroy rbST that might be in milk, is digested (as are all proteins) if consumed, and is biologically inactive in the human body.

The World Health Organization, the Commission of the European Communities, the National Institutes of Health, and the FDA have independently stated that dairy products and meat from bST-treated cows are safe for human consumption. Although rbST is banned in Canada, the European Union, Japan, and Australia, these countries reconfirmed the safety of rbST-supplemented cows. These countries allow milk and dairy products from rbST-supplemented cows to be marketed in their countries with no special labeling requirements.

Environment

The world is faced with a growing population with a growing need for food (see “► [Food Security](#)”). As countries become more developed, the increase for animal products increases. Limited resources and the greenhouse effect are an increasing concern (Flachowsky 2011) (see “► [Climate Change, Ethics, and Food Production](#)”).

Cows do produce methane gas as a result of the microbes in their rumens. Cows must be credited, however, for the conversion of cellulosic-based materials as forages (where row crops cannot be grown) and our waste products (citrus pulp, distillers' grain, soy hulls, etc.) to high-quality proteins for human consumption. Ironically cows fed a forage-based diet will produce more emissions per unit of milk than those fed a more grain-based diet. Technology must continue to evolve and be used to improve dairy's carbon footprint, if dairy products are continued to be favored by consumers. The use of rbST as a tool to aid in the sustainability and lessening of environmental impact is gaining increasing attention, mitigating environmental impact, while continuing to produce a healthy product for an ever growing population. Effect of rbST is on metabolism of nutrients, specifically a shift of the use of nutrients for milk production. For the environment, rbST works best if the number of cows is reduced to maintain production, not increasing production. Capper et al. (2008) did a simulation analysis of what is the impact of the use of rbST on 1,000,000 cows compared to the impact of cows producing the same amount of milk as the rbST-supplemented cows (Table 1).

This example clearly shows a reduction in the use of fossil fuels and water, with a reduced carbon footprint. If we consider the total amount of animals used from a utilitarian point, this model would also reduce the amount of animals used by over 10 % for the same amount of product.

Conclusion

Choosing whether or not to consume dairy products (and the resultant meat products that result) was not an issue discussed here. Despite this, it is obvious that there is still a multitude of welfare (ethical concerns) for the dairy cattle. Many of these concerns are the same, regardless of the size of the farm, although magnitude may differ. Issues were presented for starting discussions for potential agreement of the issues, so that problems presented can begin to be resolved.

Dairy Production: Ethical Issues, Table 1 Annual resource inputs, emissions, and waste output from a group containing one million rbST-supplemented dairy cows^a compared to equivalent milk from an unsupplemented group (Used with permission from Capper, J. L., Castaneda-Gutierrez, E., Cady, R. A., and D. E. Bauman. (2008). The environmental impact of

recombinant bovine somatotropin (rbST) use in dairy production. Proceedings of the National Academy of Sciences of the USA, 105, 9668–9673. www.pnas.org/cgi/doi/10.1073/pnas.0802446105. Copyright (2008) National Academy of Sciences, USA; not all inputs and outputs are reproduced)

	Without rbST	With rbST	Reduction with rbST use
Production parameters			
Milk production (kg/year × 10 ⁹) ^b	14.1	14.1	0
Lactating cows (× 10 ³)	1,338	1180	152
Waste output			
Nitrogen excretion (t/y × 10 ³)	100	91	9.6
Phosphorus excretion (t/y × 10 ³)	45.7	41.4	4.3
Gas emissions			
Methane (kg/year × 10 ⁶) ^b	495	454	41
Nitrous oxide (kg/year × 10 ³)	100	91	9.6
Total carbon footprint (kg CO ₂ /year × 10 ⁹) ^c	21.6	19.7	1.9
Resource use			
Fossil fuels (MJ/y × 10 ⁶) ^d	8,840	8,111	729
Electricity (kWh/y × 10 ⁶)	1,350	1,195	156
Water (l/y × 10 ⁹)	66.9	61.5	5.4

^aOne million lactating cows supplemented with rbST plus associated ineligible lactating cows (too early in lactation), dry cows (not lactating), and replacement heifers. The average unsupplemented cow had a lactation average milk yield of 28.9 kg/day, and the milk response to rbST was +4.5 kg/day

^bIncludes CH₄ from enteric fermentation and manure fermentation

^cIncludes CO₂ emissions from animals and cropping, plus CO₂ equivalents from CH₄ and N₂O

^dOnly includes fuel used for cropping

Derrida and Eating

Kelly Oliver

Hospitality and food; Meat: ethical considerations

Introduction

Jacques Derrida makes an analogy between eating other beings or substances and assimilating others' values and ideals. He makes a distinction between assimilating others – whether food or other people – in ways that nourish and ways that conquer them as trophies. Through this analogy, Derrida is concerned to develop an ethics that respects one's differences from others while acknowledging that one needs to eat or assimilate others in order to live. He makes a connection regarding what is good to eat in both physical and moral senses.

What Is Good to Eat?

In the interview "Eating Well," Derrida wonders whether a head of state (*chef d'Etat*) could gain office by declaring him (or herself) a vegetarian and concludes, "the chief (*chef*) must be an eater of flesh" (Derrida 1991, p. 114). In the United States, political leaders are often seen hunting, particularly bird hunting, which seems to demonstrate their manly fortitude and bloodlust that can keep citizens safe. Hunting itself as a trope has become a trophy of sorts within the rhetoric of political image making. And meat eating or eating flesh is a sign of strength and fortitude. It is interesting to note that Derrida was an "eater of flesh." In this same interview, Derrida associates eating well with ethical obligations that separate moral and physical nourishment from trophies. There, Derrida maintains that the oppositional limit between animal and man, and even between living and nonliving, has been challenged to the point

that the ethical question in relation to animals is not whether they are subjects, sentient or feeling, and so forth and therefore should not be killed but rather how to eat them in the most respectful way. For Derrida, one can no longer draw rigid borders between humans and animals because one can no longer define any absolute boundary between self and other. The question of the relation between man and animal comes back to the question of the relation between the self or subject and the other. He concludes:

...the question is no longer one of knowing if it is 'good' to eat the other or if the other is 'good' to eat, nor of knowing which other. One eats him regardless and lets oneself be eaten by him... The moral question is thus not, nor has it ever been: should one eat or not eat, eat this and not that, the living or the nonliving, man or animal, but since *one must* eat in any case and since it is and tastes good (*bien*) to eat, and since there's no other definition of the good (*du bien*), how for goodness sake should one *eat well* (*bien manger*)? (Derrida 1991, pp. 114–115)

By *eating*, Derrida means not only the physical act of ingesting food but also the metonymical act of interiorizing symbols, language, and social codes. Experience and sensation are also implicated in this eating. All forms of identification and assimilation in relations to the Other (language, meaning, and so forth) and others (including animals, plants, rocks, and so forth) are literal and/or metaphorical forms of eating. Derrida argues that all relationships invariably literally or symbolically assimilate the other; assimilation is necessary not only for war but also for communion and love: communication depends upon the assimilation of the Other (especially language and meaning) and others (friends, family, and loved ones). One learns language through assimilating words, one understands others and communicates with them by assimilating traditions and values, and so forth. Both words and food move through the orifices of the body, most particularly the mouth.

Derrida says "as concerns the 'Good' (*Bien*) of every morality, the question will come back to determining the best, most respectful, most grateful, and also most giving way of relating to the other and of relating the other to the self" (Derrida 1991, p. 114). For Derrida, the *good* of morality or ethics is explicitly linked with the *good* of eating

as in *tastes good* and *eating well*. Derrida emphasizes that one *must* eat. It is both a need and a desire, and the *must* is both a natural necessity – living organisms must eat to live – and a moral obligation; in some cultures suicide, even by starvation, is considered immoral. In addition, all community or communion requires some form of assimilation – common language and customs – that Derrida metonymically links to eating. One must eat. And since one must eat both by need and by desire, the question is not whether or not to eat but how to eat.

What to Eat and How to Eat

Derrida presses the question of what to eat given that ultimately any lines one might draw between man and animal, animal and vegetable, living and nonliving are always fluid and open to debate. The “what” of “what should one eat?” is a moving target as both needs and desires change: one is told to change diets for the sake of life and health, and customs and sensibilities oblige one to make dietary changes for the sake of ethical obligations to other creatures and renewing the resources of the planet. Also, on the metonymical level, languages and symbolic resources are shared. So the question of what to eat is never answered once and for all; it has to be continually asked in the vigilant, and ultimately undecidable, way required by hyperbolic ethics. Following Emmanuel Levinas, Derrida proposes what he calls *hyperbolic ethics* in order to insist on urgency and the necessity for constant vigilance. Its imperatives and responsibilities are hyperbolic because they demand the impossible: that one be hyper-aware of the ways in which actions and decisions fall short of ideals. Like the infinite curve of a hyperbola, we can only continue to approach the asymptote that is our ideal. Moreover, we must be hyper-aware of the ways in which ideals themselves exclude others, even others whom one may not recognize. So, although one must eat, one also has an ethical obligation to decide how to eat in a way that respects others, even those whom one ingests. Moreover, one must choose a style of eating, a lifestyle, in the face of ultimately undecidability and uncertainty about relations to others. In other words, the question of “what” is a metaphysical question that is essentially

undecidable; a question that must be answered but cannot be answered with any certainty. The question, then, “is it good to eat?” is fraught with ambiguity in the face of which one has ethical obligations that one does not even recognize as such. The ethical question par excellence for Derrida, then, is not whether or what but how: how to eat-assimilate well. It is crucial, however, to point out that the questions of what and how are intimately linked. One decides how to treat other beings on the basis of presuppositions, beliefs, and conclusions about *what* they are: are they sentient, are they human, are they capable of suffering, etc. *How* one treats them – or eats them – is determined in large part by *what* they are.

Does Deconstruction Imply Vegetarianism?

Discussing Derrida’s ambivalence toward vegetarianism, philosopher David Wood says, “Derrida is reported to have said at the Cerisy conference in the summer of 1993, ‘I am a vegetarian in my soul’. The proper place for vegetarianism is not in the soul but in a complex reworking of the investments of the oral sphincter and all its personal and political ramifications. Carnophallogocentrism is not a dispensation of Being toward which resistance is futile; it is a mutually reinforcing network of powers, schemata of domination, and investments that has to reproduce itself to stay in existence. Vegetarianism is not just about substituting beans for beef; it is – at least potentially – a site of proliferating resistance to that reproduction” (Wood 1999, pp. 32–33). Against what he suggests may be Derrida’s “beautiful soul,” Wood argues for vegetarianism as a “symbolic substitute for unlimited and undelimitable responsibility – the renegotiation of our Being-toward-other-animals” (Wood 1999, p. 32). Wood refuses to accept what seems to be suggested by Derrida’s remark that “vegetarians, too, partake of animals, even of men.” It is not so much that Wood denies that vegetarians also participate in systems of domination and live in various essential ways off of killing and eating animals, including other human beings.

Rather, on the one hand, Wood imagines a more “deconstructive” form of vegetarianism – or perhaps a more vegetarian form of deconstruction – through which one might rethink all relationships to others; and on the other hand, he insists that there is a difference between eating beef and eating beans that cannot be so easily disregarded, even in the name of keeping vegetarians honest. In other words, although all are implicated in killing and eating the flesh of others, it still matters ethically and politically whether or not one decides to eat beef or beans. As Wood insists we have to be able to distinguish really eating animals from eating them symbolically. Even if, as one learns from Derrida, conceptually the real and the symbolic are inseparable (they have their meaning only in relation to each other), on the level of practical ethics and politics, it is imperative to keep them distinct, which, according to Derrida, can be done only by acknowledging the ways that one is implicated in the other. In other words, one can separate really eating from symbolic eating only by recognizing how the two are always already mixed.

In his criticisms of Wood, philosopher Matthew Calarco emphasizes this later aspect of deconstruction, namely, that one cannot stop questioning investments in killing others, including other animals and other people, just because one quits eating meat. Deconstruction, as Calarco suggests, requires ongoing self-interrogation into both how and what to eat. The ethics of deconstruction must radically question what Calarco calls “the undisclosed anthropocentric and carnophallogocentric limits of the dominant discourses in animal ethics and vegetarianism,” which base human responsibilities to other animals on similarities with them (Calarco 2004, p. 197). Calarco concludes that deconstruction may provide a way of thinking about ethical obligations to animals beyond what one might call taking the easy way out by finding similarities. While deconstruction may provide a much needed antidote to rights discourse based on identity, Calarco’s beef with Wood sometimes seems to degenerate into a debate over the virtues of veganism over vegetarianism. As both Calarco and Wood acknowledge, however, Derrida’s point is that ultimately where the line is drawn between

oneself and others is radically undecidable in any certain metaphysical terms and yet at the same time unavoidable. Ethics cannot be founded on counting how many species are sentient or suffer, whether one eats shellfish or so-called animal products like dairy. What about bacteria, viruses, and fungus that feed on humans? Aren’t they living beings too? Should one kill them? Can one be open even to the other who feeds? Derrida is adamant that an extreme ethics allows that one can never know from where – or from whom – an ethical call will be heard. Ethical responsibility is motivated by radical differences that multiply rather than diminish or calculate the species of ethical calls. Derrida seems to ask “Can we eat the other in a way that nourishes her as well as nourishes us?” In other words, is there a virtuous way of eating the other? This question involves both the how and what, not to mention the why, of ethical eating.

Eating Well

For Derrida, ethics comes down to the question of eating well or in a sense good taste. Derrida says “The Good can also be eaten. And it must be eaten well” (Derrida 1991, p. 115). It is not just a matter of interiorizing or assimilating the Good but rather learning the lesson well, taking it to heart, but not by making it second nature or habit. Eating well requires vigilance and must resist becoming merely a habit. If it does become a habit, then it is no longer ethical because it does not continue to question and to “learn.” If morality becomes a habit, then one is like a trained animal, reacting rather than responding. Derrida takes the ideal of the pure heart and embraces it, but only in its impossibility; it is precisely this impossibility of the pure that separates (radical or pure) ethics from morality. But for Derrida, taking to heart is an impossible ideal that can never be realized, yet must be attempted anyway and always. Indeed, if it were realized in the sense of becoming a moral or mental habit, then it would no longer be ethical. In Derrida’s writing, the romantic faith in the purity of nature becomes a rejection of that very purity in the name of an impure purity or a taste

for impossible purity, forever deferred, a purity of the future, a purity to come. For Derrida, an ethics that remains open to surprise or open to the other requires giving up moral habits along with the notion that morality is a matter of habit. Doing good as a matter of habit or convention reduces ethics to nothing more than a reaction to stimuli, and man becomes a well-trained horse or dog, doing clever tricks to impress his master.

In spite of his departures from the romantics, Derrida embraces ideals of generosity that suggest the individual's inherent and intimate relations with others. Derrida says that in order to be good, food must be shared. To eat well, one must share not only food but also nourishment; one has an obligation to attend to the other's nourishment even as one feeds oneself:

The infinitely metonymical question on the subject of 'one must eat well' must be nourishing not only for me, for a "self," which given its limits, would thus eat badly, it must be shared, as you might put it, and not only in language. 'One must eat well' does not mean above all taking in and grasping in itself, but learning and giving to eat, learning-to-give-the-other-to eat. One never eats entirely on one's own: this constitutes the rule underlying the statement, 'One must eat well.' It is a rule offering infinite hospitality. (Derrida 1991, p. 115)

In this regard, one could learn something about eating well at table from the metonymical "eating" of speaking and vice versa (there is no private language), or one could say that to speak only to oneself or for oneself is to speak badly because (even when talking to oneself) language presupposes an addressee. Language entails response ability insofar as it is always addressed to someone, in particular or in general, near or far, radically other (like the time capsules launched into space from earth intended for extraterrestrials) or the other within the self. The "must" of "must eat" compels hospitality insofar as eating well is a social experience. Obviously food is the heart of many social and familial gatherings and events, and it is usually the result of some sort of cooperation or exchange in that (in developed countries) very few people eat only the food that they produce themselves (indeed, it would be a mighty task for one individual alone to produce – grow, harvest, cook, and so forth – all of the foodstuffs

that he consumes). The ethics of eating well, then, seems to imply a politics of food through which one attends to how one acquires nourishment. Derrida's eating well may have something to say to "slow food" and "local food" movements. In addition to food, languages, cultures, customs, and love are also shared, which more obviously raise political questions about English-only policies, multiculturalism, and globalization.

Hospitality and Eating with Others

Unfortunately, more often than not, the cooperation and social exchange that allow one to eat is built on exploitation within an economy of exchange that makes everything fungible. The fact that eating or speaking requires a group effort or global exchange should not be confused with hospitality. In addition, the ethical obligation that Derrida describes is not just to hospitality, to sharing food and nourishment (of all sorts), but, moreover, to *infinite* hospitality. To eat well is to be infinitely vigilant in one's hospitality to the other, even the very other whom one eats. In fact, as Derrida articulates this ethical obligation, it is this "who" or "whom" that incessantly must be put into question, both on the side of the "subject" and on the side of the "other": *who* claims the rights and privileges of *whom*, of subjectivity? Who has the right to judge the subjectivity or humanity of others? Derrida calls into question the ways that subjects give themselves the right to divide the world into subjects and objects/others, man and animals, those who eat and those who are eaten (both literally and figuratively).

Derrida calls this infinite hospitality "absolute" or "pure hospitality," which he envisions as the foundation of hyperbolic ethics (e.g., 2000, p. 25; 2005, p. 249). In *Of Hospitality*, he describes the rule or law of hospitality as impossible since true hospitality cannot be dictated by law, custom, habit, or training but must come "from the heart." He plays on the fact that in French *hôte* means both host and guest, suggesting the fluidity of giving and receiving. That the host can become the guest and vice versa, just as the eater can become the eaten and vice versa, indicates both the instability of power relations and the relationality of subject positions. Pure or absolute

hospitality requires giving up the illusion of being at home or owning a home in which one can play host.

The Limits of Nourishment

In his first posthumously published book, *The Animal That Therefore I Am* (Derrida 2008), Derrida calls his project a limitrophy, and he draws out the etymological associations of the word *trophe*, which takes one back to eating: “In the semantics of *trepho*, *trophe*, or *tropos*, we should be able to find everything we need to speak about what we should be speaking about. . . : feeding, food, nursing, breeding, offspring, education, care and keeping of animals, training, upbringing, culture, living, and allowing to live by giving to live, be fed, grown, autobiographically” (Derrida 2002, p. 398). Derrida goes on to point out that “the first literal sense of *trepho*” is “transforming by thickening, for example, in curdling milk” (398).

One could say that in Derrida’s limitrophy, paradoxically, the purity demanded by hyperbolic ethics requires the curdling or thickening of frontiers, borders, or limits. This curdling leaves them in a liminal state between fluid and solid, which opens the border onto multiple forms beyond two defined as one side of the limit or the other. Derrida seems to challenge the limits of solid borders, which appears within the history of philosophy as fixed, rigid, and pure, in the name of pure fluidity, which is, of course, impossible. In the name of pure fluidity, Derrida continually points to the curds, those strange substances that cannot be properly classified as solid or liquid. Ironically, perhaps, the “purest” forms turn out to be thickened or curdled, the in-between substances that are neither purely liquid nor purely solids. Derrida seems to prefer curds and curdling to either solids or fluids (as a metaphor for his attempts to navigate between absolutism and relativism). He embraces the ambiguities of life even while maintaining some notion of purity. In this way, Derrida endorses an ethics motivated by *trophe* or nourishment rather than *trophy* or conquest.

For Derrida, there is ambiguity between the two to the point of inseparability; in other words, nourishment is always at some level also conquest.

The double meaning of *trophe/trophy* may be instructive, however, in the necessary (if ultimately impossible) attempts to distinguish eating well or good eating from devouring the other in poor taste. *Tropho*, *tropho*, and obsolete forms of *trophe* are associated with feeding and nutrition, while *trophy* is associated with the spoils of war or the hunt that have been made into monuments. Does one kill and eat the other for *trophe*, nourishment, or for *trophy*, sport and triumph? Is one’s relationship with the other and with others nourishing, or is it a display of power and conquest? These questions can be asked on the literal level about hunting and killing animals or people and on the figurative level about assimilating speech and cultural conventions. Are some forms of assimilation wholesome and others merely for display? Hyperbolic ethics requires vigilance in continually asking how what feeds us becomes imbricated in relations of power and domination.

Derrida’s ethics cautions one not to draw this line between nourishment and triumph in a fixed or rigid way; to do so is not only to become reactionary rather than responsive but also and moreover, to shirk an ethical responsibility to the radical openness and fluidity of all moral categories. In this sense, ethics provides a kind of corrective for morality. If morality divides the world into good and evil, then hyperbolic ethics demands that one constantly questions that division and investment in it. Are these distinctions made in order to foster nourishing and healthful relationships or is the world divided in order to conquer it and take others as trophies? In terms more familiar to recent discussions in ethics one might ask, are differences circumscribed to justify hierarchies and domination or to respect them and acknowledge their value?

Derrida argues that the unity and identity of both the individual and the social bodies feed off of those very others it rejects; it both secretes its own poison and feeds off of it. Discussing the “scapegoats” cast out of the city of Athens,

Derrida remarks, “the representative of the outside is nonetheless constituted, regularly granted its place by the community, chosen, kept, fed, etc., in the very heart of the inside. These parasites were as a matter of course domesticated by the living organism that housed them at its expense” (Derrida 1972, p. 133). The scapegoat plays the role of a pharmakos, both sacrificed for and yet constitutive of humanity; the animal is both inside and out.

What hyperbolic ethics requires is that one turns the sacrificial logic back on itself and gives up the need for scapegoats and sacrificial lambs (human and animal). Hyperbolic ethics requires that one continues to question investments in discourses of purity, trying to avoid any simple conquest of others, even through the triumphant moves common to philosophy. Perhaps, in the spirit of *trophe*, one can thoughtfully assimilate the lessons of Derrida’s work in the hopes of feeding a robust ethical theory that speaks to the question of how to relate to others, including animals and other living creatures with whom the earth is shared, in ways that nourish rather than conquer.

Summary

In sum, Derrida argues that although one must eat or assimilate other living beings, there are more and less ethical ways of doing so. He is not arguing for vegetarianism but rather for a thoughtful approach to eating for the sake of nourishing oneself and others rather than for the sake of proving dominance over others or conquering them and making them into trophies. His hyperbolic ethics requires that one always remains open to reconsidering what is “good” to eat.

Introduction

Although dietary supplements are a ubiquitous part of modern life, especially in the United States, very little philosophical work has been done on the ethical issues surrounding them. This is even more surprising given that many of the specific issues with dietary supplements resonate with other contemporary debates in moral and political philosophy. The purpose of this entry, therefore, is to identify the primary moral dilemmas concerning dietary supplements, to identify the positions that previous stakeholders have taken with respect to those dilemmas, and to suggest future directions for continued research.

To those ends, this entry is divided into six sections, including this introduction. Section “[Defining Dietary Supplements](#)” investigates the definition of dietary supplements as well as some marginal instances that challenge conventional definitions. Section “[Prevalence](#)” investigates the statistical ubiquity and widespread use of dietary supplements, specifically within the United States. Section “[Abuse, Self-Harm, and Cheating](#)” discusses moral problems relating to the personal use of dietary supplements, which we divide roughly into two categories: self-harm and competitive misconduct, specifically in athletics. Section “[Oversight and Accountability to Consumers](#)” discusses moral problems relating to the regulation and oversight of the dietary supplement industry, with special attention paid to false advertising and the perils of self-regulation on the part of large companies. Finally, section “[Production](#)” discusses moral problems relating to the production and sourcing of dietary supplements, especially as it relates to species extinction and related environmental concerns.

Defining Dietary Supplements

Before discussing the ethical problems concerning dietary supplements, we must define the concept itself. This is no mean feat, however, as the nature and social significance of dietary supplements invites frequent redefinition and challenging new

cases. Although US law does explicitly define dietary supplements, as we will see, there is room to clarify and refine this definition.

In simplest terms, dietary supplements are substances that are ingested for the purpose of augmenting nutrition and that are neither foods nor medicines. The paradigmatic example of a dietary supplement is the multivitamin. Typically, a multivitamin is a pill that contains a variety of nutritionally valuable substances like minerals and herbs. It is not uncommon for a company that markets multivitamins to offer a variety of pills that combine different ingredients and amounts to cater to the dietary needs and nutritional deficiencies of different people at different stages of life – one for children, another for postmenopausal women, etc. Typically, dietary supplements come in the form of pills, whether capsules or tabs, but may also be powders, liquids, and possibly sprays.

The term “dietary supplement” was officially defined as part of US law in the Dietary Supplement Health and Education Act of 1994 (DSHEA) (Onel 2005). Whether to its credit or detriment, the legal definition bears a close resemblance to the simple definition above. The language of the law, omitting some details, is as follows:

“The term ‘dietary supplement’

1. Means a product (other than tobacco) intended to supplement the diet that bears or contains one or more of the following dietary ingredients: (A) a vitamin, (B) a mineral, (C) an herb or other botanical, (D) an amino acid, (E) a dietary substance for use by man to supplement the diet by increasing the total dietary intake, or (F) a concentrate, metabolite, constituent, extract, or combination of any ingredient in clause (A), (B), (C), (D), or (E);
2. Means a product that (A) is intended for digestion. . . , (B) is not represented for use as a conventional food or as a sole item of a meal or the diet; and (C) is labeled as a dietary supplement; and
3. Does. . . (B) not include (i) an article that is approved as a new drug. . . or, (ii) an article authorized for investigation as a new drug.” (US Congress 1994)

Dietary supplements are typically and legally distinguished from foods and medicines. Unlike foods, dietary supplements contain few if any calories and so cannot provide the energy necessary for a normally functioning body. One cannot survive on supplements alone. Similarly, dietary supplements are typically distinguished from drugs and medicines. Here the distinction is more challenging to discern. One might propose, for instance, that drugs and medicines are intended to change the inner processes of the body, while supplements are only meant to enhance or facilitate ongoing bodily processes.

However, it is unclear that either of these distinctions withstands scrutiny. To the difference between supplements and food, it seems that there are substances that belong squarely in the category of food, like celery, on which one cannot survive alone. But surely celery is a food and would still be even if it were marketed as a supplement. The distinction between drugs and supplements is similarly complicated by, for example, “medicinal herbs.” Traditional and holistic forms of medical care consider some substances medicines that, by legal definition, are categorized as supplements.

Despite being relatively esoteric, there are real stakes in how dietary supplements are defined. In the first place, because dietary supplements are partially defined in contrast with drugs and medicine, the determination of what *is* a dietary supplement also established what *is not* medicine. This subtle semantic point suggests the substantive normative judgment that conventional western medical practice, which is generally skeptical toward “medicinal herbs,” deals in medicine proper and that traditional methods are pseudo-medicine or are valuable only as additions (i.e., supplements) to the conventional model. In the second place, dietary supplements are regulated differently from both drugs and foods. As a consequence, companies can have significant economic interests in how their product is categorized and in any proposed changes to the legal categories.

Prevalence

Dietary supplements are commonplace in the United States, and their use is prevalent across demographics. The National Health and Nutrition Examination Survey (NHANES) is a nationally representative, cross-sectional survey designed to assess health and nutritional status of Americans through the use of interviews and physical examinations (NHANES 2016). NHANES 2003–2006 determined the incidence of use of dietary supplements among adults and children to be 49 % of the US population, about 10 percentage points greater from NHANES completed in 1988–1994 (Bailey et al. 2011). Women were more likely (53 %) to report using dietary supplements compared to men (44 %), and multivitamin, multimineral (MVM) supplements were reportedly used most prevalently (33 %). Other demographic considerations of note include that surveyed individuals who reported using dietary supplements were also mostly healthy weight BMI, mostly had been educated beyond high school and were mostly non-Hispanic white.

A 2009–2010 survey conducted at five US universities included 1,248 college students, and approximately 66 % of surveyed students reported use of a dietary supplement at least one time per week for the 6 months prior to the survey (Lieberman et al. 2015). Respondents who consumed a high-protein and low-fat diet were more likely to take any dietary supplement. Students who consumed a high-protein diet were more likely to take five or more dietary supplements per week, multivitamins or multiminerals, protein, and amino acids and spend more than \$30 per month on dietary supplements. The most frequent reason for dietary supplement use was to promote general health (73.3 %), but other significant reasons included the desire for a supplement to provide more energy (29.1 %), greater muscle strength (20.4 %), and enhancing athletic performance (18.9 %).

In 2007 \$2.9 billion was spent on homeopathic medicine (which includes, but is not limited to, remedies derived from plants, metals, and minerals), and \$14.8 billion was spent on non-vitamin, non-mineral, natural products

(defined as orally consumed and supplementing the diet, but not vitamins or minerals, e.g., ginkgo biloba, echinacea, ginseng) (US Department of Health and Human Services 2011). The National Center for Complementary and Integrative Health (NCCIH), a division of the National Institutes of Health (NIH), contextualizes that this expenditure is equivalent to approximately one-third of total out-of-pocket spending on prescription drugs.

Although dietary supplements are an everyday part of many people's lives, specific products will occasionally experience intense public attention. Frequently this is the result of endorsement from a popular celebrity figure. Anna Nicole Smith's endorsement of TrimSpa and Khloe Kardashian's endorsement of Garcinia Cambogia, both advertised as weight loss supplements, are two examples (Demarrais 2007). In other cases, public attention is attracted by extreme physical accomplishments and scandal. The highest profile examples frequently come from athletes. Mark McGuire's use of androstenedione (which was considered and regulated as a dietary supplement until it was reclassified as a controlled substance under the Anabolic Steroid Control Act of 2004) during his record-breaking baseball season is one example (Denham 2006). Lance Armstrong's use of "oil," a testosterone supplement mixed with olive oil that was frequently administered to him orally, is another. Indeed, sports have become one of the most familiar arenas for the abuse of dietary supplements (McNamee 2007; Outram and Stewart 2015).

Abuse, Self-Harm, and Cheating

Because dietary supplements can create significant changes in our bodies, they have significant potential for abuse, and their abuse raises serious moral questions. Ethical problems concerning the abuse of dietary supplements can be helpfully divided into two categories: self-harm and unfair advantage. These categories may overlap and should not be treated as exhaustive. Very little scholarly work has been done on the ethical issues surrounding the abuse of dietary supplements, but this section will briefly explore what seem to us to be promising avenues of inquiry.

The first way that dietary supplementation can be abusive is when it results in self-harm. Three salient examples of self-harm through supplements are the overuse of weight loss pills, the overuse of testosterone precursors, and the ingestion of harmful chemicals like dimethylamylamine, which was linked to the death of a military private in Fort Bliss, TX in 2011 (Smurawa and Congeni 2007; Palmer 2014). The side effects of diet and weight loss pills vary, as their contents vary, but can include chest pain, insomnia, headaches, elevated risk of heart attacks, and more (Cohen 2009; Curfman et al. 2010). Use of testosterone and testosterone precursors has been linked to impaired fertility and elevated risk of heart disease, particularly among men (Bonetti et al. 2008). The extent to which consumers are aware of the risks they take when they use weight loss pills or testosterone precursors is unclear, though the prevalent use of both among adolescents suggests that a fair number of users likely are not aware (Smurawa and Congeni 2007; Stephen et al. 2014).

One moral question we might ask in this context is whether it is permissible for a person to harm his or herself by abusing dietary supplements. Despite the attention paid to harm, particularly because of the concept's central role in John Stuart Mill's work, the limited scholarly work on the ethics of self-harm has primarily focused on salient cases like private drug use and suicide. Much of this work focuses on whether governments have a right to intervene and prevent self-harm (Wilson 1990; Husak 2000; De Marneffe 1996; Corlett 2013). On one side of the debate is the argument that individuals have a natural right to control their own bodies, which includes the substances they choose to put into those bodies (Husak 1989, 2000). On the other side are arguments that concerns about public health and safety override that right and justify government intervention (Wilson 1990; Corlett 2013). In both camps, however, the presumption seems to be that the right to harm oneself exists and that it is permissible to do so absent countervailing considerations. Whether or not a person has a right to self-harm is more hotly contested in the literature surrounding suicide (Thomson 1999).

While these analogous cases could be helpful to specific analysis of whether it is permissible to harm oneself by abusing dietary supplements, the complexity of the influence that supplements have on our bodies poses a specific challenge here. Four cases demonstrate this point: (1) The user knows the risks and takes the supplement hoping that those side effects will eventuate; (2) the user knows the risks and hopes the side effects will not eventuate; (3) the user does not know the side effects, but has the requisite knowledge and access to find out what they are; and (4) the user does not know the side effects and lacks the requisite knowledge and access to find out what they are. Case 1 poses a question about the ethics of masochism and is perhaps most fruitfully analogous to debates about suicide. Case 2 asks whether it is wrong for a person to risk their health and well-being for the sake of some other good and so is perhaps most analogous to drug use. Case 3 poses a question about negligence and whether consumers can be held morally responsible for taking unknown risks. Case 4 poses a question about personal responsibility in a state of ignorance.

The second and perhaps more widely discussed example of abusing dietary supplements is when athletes use them to gain unfair advantage in competition (Schermer 2008). Famous examples are the aforementioned Mark McGuire in baseball and Lance Armstrong in cycling. Supplements like Armstrong's "oil" were prohibited by the body governing cycling, and it was unfair for him to use such a banned substance when his competitors did not out of deference to the established rules of engagement, so to speak. One problematic consequence is that cheating in this way will induce other competitors to cheat and so undermine the values that we hope to encourage in sport (Murray 1987). Others argue that cheating in sport using biomedical enhancements like specialty supplements, especially expensive ones, could create a performance rift between competitors who can and cannot afford them, thus reducing success in sport to economic standing rather than talent (Sparrow 2011).

There is some debate about whether enhancements, like some currently banned dietary

supplements, ought to be allowed in sport (Schermer 2008; Petersen and Kristensen 2009; Savulescu et al. 2013). Their use only gives unfair advantage currently because they are prohibited by the rules of the sport – but those rules can be changed. Some have suggested that those rules should be changed and have put forward the idea of a “Super Olympics,” which would allow athletes to compete using the most cutting-edge enhancements available (Munthe et al. 2000). Others have argued against, claiming that enhancements and doping undermine the purpose and fundamental values of athletic competition (Schneider and Butcher 1993).

Oversight and Accountability to Consumers

Despite their widespread use and significant potential for abuse, dietary supplements enjoy relatively little oversight and regulation. According to one scholar, referring to the DSHEA, “In 1994, the manufacturers of dietary supplements got a free pass allowing them to make over-the-top, unsubstantiated claims for their products with no oversight from the FDA,” (Tao 2009). According to another, again speaking about the DSHEA,

Multiple challenges in regulatory enforcement have significant public health consequences, including inadequate evaluation of safety, insufficient requirements for efficacy, minimal surveillance for unsubstantiated labeling and marketing claims, poor quality assurance and control, and gaps in reporting of AEs [adverse events] in the context of a post-market regulatory framework. (Starr 2015)

The DSHEA significantly reduced the FDA’s ability to regulate dietary supplements. Prior to the DSHEA, whether a supplement was regulated as a drug or as a food was largely left to the determination of the manufacturers. The passage of DSHEA resulted in dietary supplements being regulated as foods (Palmer 2014). According to one scholar,

Unlike the strict regulations that govern pharmaceuticals, however, the dietary supplement market under the DSHEA functions with fairly relaxed requirements. In fact, dietary supplements do not

even require pre-approval before being released for sale to the public. The DSHEA sets up a reactive system that holds manufacturers responsible for guaranteeing safety for their products *before* they are released unto the market, whereas the FDA is not responsible for taking action against unsafe products until after they are being sold to the public. (Palmer 2014, p. 315).

In 2011, President Obama signed the Food Safety Modernization Act (FSMA), which authorized the FDA to “detain” a dietary supplement or food not only in the presence of evidence that it posed a serious health threat (which the FDA already had under DSHEA) but also when presented with evidence that the product was adulterated or misbranded (Palmer 2014; Voice 2016). This has allowed the FDA to be significantly more proactive and to move toward regulating supplements before they cause harm, rather than only after the fact.

One dramatic example of the consequences of lax regulation came in February 2015, when the New York State attorney’s office revealed that, when tested, approximately four out of five herbal supplements purchased from major distributors like Walgreens, Walmart, and GNC were found not to contain their advertised herbs. According to the New York Times,

The tests showed that pills labeled medicinal herbs often contained little more than cheap fillers like powdered rice, asparagus and houseplants, and in some cases substances that could be dangerous to those with allergies. (O’Connor 2015)

There is quite a lot of work to be done by moral and especially political philosophers with respect to the regulation and oversight of dietary supplements. One moral question at stake here is the extent and form of regulation that would be justified. There appears to be little question that dietary supplements frequently do not contain what they advertise, that companies that stand to benefit from the sale of dietary supplements frequently misrepresent their products to consumers, and that this trend is the product of or at least could be curtailed by changing lax regulations or by taking other measures to discourage deceptive market practices. It would be helpful for political philosophers to disentangle these issues and to provide suggestions for how different forms of policies

might effectively address each of these and what the social costs of regulation might be.

To a large extent, the moral issues that face the marketing and regulation of dietary supplements appear to be identical to other consumable goods (Attas 1999), but some scholars have identified unique aspects of dietary supplements that demand specific attention (Palmour and Racine 2011). One specific case is the direct-to-consumer marketing of dietary supplements to Alzheimer patients. Marketing to cognitively impaired consumers is morally problematic in the first instance, but because dietary supplements can be advertised as alternative medicine, they expose those consumers to the additional risks of forgoing effective treatments in favor of what they have been deceived into believing are cheaper or otherwise more convenient alternatives.

Production

Though it has received almost no attention among scholars, and almost certainly not among ethicists, there are also significant moral issues in the production of dietary supplements, primarily concerning environmental and endangered species conservation but also with respect to labor conditions in the manufacturing process.

The production of dietary supplements necessitates in many cases harvesting wild or rare natural resources, and this can create threats to the continued viability of specific species or whole biotic communities. Goldenseal, an herb advertised to improve immune functioning, is a perfect example. According to a USDA report, “Goldenseal is perceived to be at high risk of extinction due to excessive harvesting of wild populations to supply the market,” (Henson 2001). Shark cartilage and shark liver oil, ingredients used in dietary supplements and cosmetics, pose similar threats to a variety of shark species, according to a report by the UN Food and Agriculture Organization (FAO) (Kuang 1998).

One particularly salient example of the destructive potential of morally questionable practices in the production of dietary supplements is rhinoceros horn powder. The powder, made

from ground horn of the African black rhinoceros, is used in traditional Chinese medicine to cure a variety of physical ailments and to augment virility (Ellis 2005, pp. 101–102). The population of black rhinoceros has shrunk considerably in recent decades, fueled primarily by poaching, and the species is considered “critically endangered” by the World Wildlife Federation (World Wildlife Fund 2016). The driving force behind poaching is, unsurprisingly, international demand and willingness to pay large sums of money for the horns. Unaddressed, the species may well go extinct.

This case represents a variety of moral issues. The first concerns the moral significance of species extinction. There is room for philosophers to disagree about whether or why species extinction represents a significant moral problem. While adherents to a variety of leading environmental ethics, specifically deep ecology and the land ethic, might judge that species extinction represents something intrinsically wrong, more anthropocentric views might withhold judgment until presented with persuasive evidence that the extinction of the relevant species would adversely affect humans (Naess 1973; Leopold 2001). The second moral problem concerns the significance of morally questionable production practices for government and consumers. Even supposing that the production of such supplements is in fact immoral, it is unclear who bears the moral responsibility – poachers, consumers, or government. It is equally unclear who bears the moral burden of rectifying the situation.

Conclusion

There is much work yet for ethicists to do concerning dietary supplements. One major contribution philosophers can make in this area is to contribute to the disambiguation of the concept itself, which is a necessary prerequisite for meaningful regulation and oversight. Dietary supplements offer a unique but clear opportunity for interdisciplinary research, as the complexity of their chemical and social natures must be understood and respected before movement is possible.

Introduction

Dogs are the first animals known to be domesticated by humans. Archaeological and genetic studies have postulated different dates for the origin of dogs, but it seems certain dogs were domesticated no later than 15,000 years ago, a date prior to the development of agriculture. Dogs are one of the most versatile species domesticated by human beings, serving in many roles within human societies – companions, guards, hunting assistants, transportation, beasts of burden, and even as food animals (Morey 2010). Archaeological, historical, and ethnographic accounts demonstrate that dogs have been used as food animals for millennia, a practice which continues to the modern day. And yet, dogs remain a rare example of an animal that has achieved a nearly universal quasi-human social status. Even in dog-eating societies it is not unheard of to have ritualistic burials of dogs, similar to that of humans, and certainly absent for other food animals (Morey 2010). The

paradox of dogs and their role in human society, both as friends and as food, makes the issue of eating dogs commonly invoked in broader discussions of eating meat and other human uses of animals.

Dogs as Food Animals

Dog meat has long been part of the human diet. Containing approximately the same amount of protein as pork, dog meat was a historically common food in the Americas, the Pacific, Africa, and East and Southeast Asia, with dog-eating cultures found on every continent (Simoons 1994). Harris (1998) suggests that dog meat consumption is most common in places that lack large domesticated herbivores. Dog meat remains most prevalent today in Asia, although this may be more of an artifact of the expansion of dominant religions and cultures with the dog meat taboo into other regions of the world than a specific survey of modern tastes. Eating dogs does not seem to correlate with negative views of dogs. Cultures that eat dog meat often engage in the same pet keeping practices as those that do not, giving dogs names, allowing them to occupy the family dwelling, and providing them with after-death rituals like burial (Morey 2010; Podberscek 2009). The dog meat taboo appears the strongest in those cultures that view dogs as unclean or undesirable rather than those that hold dogs in high esteem (Simoons 1994). Dog meat is often considered to be a delicacy, something to be served to guests or for special occasions. Schwabe (1979) and Simoons (1994) present extensive reviews of historical and ethnographic accounts of eating dog meat, ranging from the ancient Near East to the modern day.

Despite the association of caring for dogs and eating their meat, there does seem to be some level of functional distinction between dogs that can be eaten and those that should not. It is not usual for companion dogs to be consumed, except in times of extreme crisis. Archaeological work from a 5,000 year old site in Indian Knoll, Kentucky, for example, shows that dogs that were given ritual burials were not those that were consumed. Dog bones with the characteristic marks of being

butchered and cooked were among the discarded inedible remains of other food species, including deer and wild turkey, while the skeletons of those that had been ritualistically buried remained intact and distinguished from kitchen middens (Morey 2010). This kind of functional distinction is common. Australian aboriginal peoples, for example, would eat feral dingoes but not those dogs that lived among them (Simoons 1994). In some places, breeds of dog were developed to specifically serve as food animals, such as a breed of hairless dog, the Xoloitzcuintle, that was one of the primary domesticated meat-providing species of the Aztecs (Schwabe 1979). In modern South Korea, dog types are also differentiated, with certain breeds seen as suitable for pets and other kinds of nonfood uses, and others seen as suitable for meat but not for companionship (Podberscek 2009).

Harris (1998) maintains that dogs are only used as food animals when there are insufficient alternatives of either other domesticated food animals or wild game. Societies in which dog consumption are common frequently occupy places where animal protein is difficult to obtain because of historically large populations (East and South Asia), where other domesticated food animals are rare or nonexistent (the Americas and the Pacific), or where wild prey animals are scarce or difficult to hunt (pre-Islamic North Africa). Although not a perfect correlate, dog eating does tend to be a more common practice in places with animal protein scarcity or as a traditional dish among cultures with historical protein scarcity issues. Even in South Korea, where 83 % of adults have eaten dog meat at some point in their lives, most people report consuming it only two or three times a year (Podberscek 2009).

In addition to being considered a mundane food, dog meat is also consumed because it is considered to be endowed with special properties. Modern South Koreans view dog meat as having valuable medicinal properties, giving the ability to increase stamina in the midst of summer heat, improve male virility, and even treat depression. Nongustatory reasons accounted for 59 % of the reasons for consuming dog meat in South Korea, with 25 % reporting they consumed it to be sociable and 32 % citing health (Podberscek 2009). In

some parts of Equatorial Africa, dog meat also has an association with spiritual and curative powers (Simoons 1994). The use of dog meat as medicine or an edible totem exists even in cultures that generally prohibit eating dog meat as an ordinary food. In certain Buddhist tantric texts, for example, adept practitioners are encouraged to consume taboo foods, including beef and dog meat, although it is not entirely clear if such instructions were meant to be taken literally (Wedemeyer 2014). Among the ancient Egyptians, consumption of dog meat was forbidden, but dogs were butchered for the creation of externally applied medicines (Simoons 1994).

Dog Meat Taboo

Despite the historical and modern use of dogs as food animals, there remains a common and persistent taboo against dog meat in many cultures. In the Abrahamic traditions, dog meat is included among the unclean foods forbidden to the Israelites in the Torah by virtue of the carnivorous nature of dogs and their lack of a cloven foot (Leviticus 11). Although not explicitly forbidden by the Qur'an, dogs are considered unclean and unsuitable for consumption by Islamic tradition. There is no explicit injunction against eating dogs in the Christian New Testament, but given the religion's Jewish heritage and long interchange with dog taboo holding Greek and Roman cultures, it is not surprising that Christian cultures largely, but not exclusively, eschew dog meat. Statistics quoted by Podberscek (2009), for example, indicate that Christian South Koreans are among those who regularly consume dog meat in the country. Indic religions (Hinduism, Buddhism, and Jainism) discourage the eating of meat in general out of respect for nonviolence (*ahimsa*) and dog meat specifically because of their view that dogs, as scavengers, are unclean animals. Despite these injunctions, however, there are examples of dog meat eating in India and throughout East and Southeast Asia, where Buddhism is a widely practiced religion. The ancient Egyptians, Persians, Greeks, and Romans all held taboos against eating dog meat (Simoons 1994).

Given the diverse list of world religions and major empire-building cultures that held taboos against eating dog meat, it should be of little surprise that the global prevalence of dog-eating regions has steadily decreased in the past two millennia. Where the dog meat taboo persists, some eating of dog still occurs, mostly in cases of famine or other chronic food shortage (Simoons 1994). Even some avid vegetarians admit that they can conceive of extreme cases where they would consider eating dog (Foer 2009). For the most part, however, the dog meat taboo seems firmly entrenched in mainstream global culture, even in East Asia, where anti-dog meat activism is not unknown (Podberscek 2009; Qin 2015).

Given the widespread evidence of dog eating among early human groups, anthropologists have speculated about two possible origins of the dog meat taboo. The first possibility is related to health. Because dogs, especially those associated with premodern human communities, are known for eating food trash, dead animals, and other potentially hazardous materials, it could be that dogs became associated with or actually transmitted dangerous pathogens. Dog meat can transmit trichinosis if not properly cooked and hydatid disease, a fatal tumorous growth caused by tapeworms, can be contracted by improper handling of dog intestines and feces (Schwabe 1979; Simoons 1994). The second possibility derives from the various other roles dogs play in human societies. Because of the utility of having dogs around, the immediate nutritional benefits of killing and eating a companion or working dog might be offset by the loss of other productive contributions such as a death would entail (Harris 1998). The ability of dogs to play other parts in society, rather than merely as food stock, might lead to a general apprehension about consuming them, especially if other meat options are available.

Dog Eating as Defamation, Dog Eating as Defiance

Food taboos, especially related to sanctioned and forbidden types of meat, are frequently used by social groups to distinguish themselves from

others (Simoons 1994). With the global spread of Islam beginning in the seventh century CE and Western cultural norms in the sixteenth century CE, the number of regions in the world where dog meat consumption is viewed as acceptable has considerably shrunk. Regions like North Africa and the Americas where dog eating was once common are now bereft of all but a tiny minority of regular consumers of dog meat. As norms against eating dog meat were globalized, those groups who persisted in the practice are viewed as uncivilized or barbaric. Global sporting events hosted by South Korea, such as the 1998 Seoul Summer Olympic Games and the 2002 FIFA World Cup, frequently unleash criticism from animal rights activists and waves of questions in the global media about the ethical status of eating dogs and/or condemning those who choose to do so (Saletan 2002).

The accusation of dog eating is often used as a term of abuse. Filipino immigrants to Hawaii, for example, were denounced as barbaric for the “culturally backward” practice of eating dog meat back in the Philippines (Okamura 2010). Dog meat even created a minor sensation during the 2012 American presidential campaign, when President Barack Obama was chided for eating dog meat when he was a child in Indonesia by supporters of his opponent, former governor Mitt Romney, who had been criticized in the media for undertaking a long trip with his family dog secured in a pet carrier on the roof of his car (Jaconson 2012).

Alongside the global rise of the dog meat taboo, however, has been a defiant self-assertion of the right to eat dog meat by members of dog consuming communities. Protests against an ongoing summer festival in the city of Yulin in China where dog meat is commonly consumed, for example, attracts both condemnation by dog meat opponents and support from those who view it as a cultural tradition (Qin 2015). When French actress Bridget Bardot vocally campaigned against dog meat in Asia, Korean restaurateurs responded by rebranding dog meat soup as “Bardot soup” (Podberscek 2009). While some traditional dog-meat-eating countries such as Taiwan and the Philippines have adopted anti-dog-meat laws, it seems that cultural forces are the

predominant force for determining whether or not dogs are consumed. In the United States, for example, consuming dog meat is legal in 44 states and yet rarely occurs (Foer 2009). In the Philippines, however, where dog meat has been illegal since 1988, the illicit production and trade of dog meat thrives (Yap 2012). In a survey of South Koreans, more supported banning the slaughter of cattle (33 %) and sheep (29 %) than dogs (24 %) (Podberscek 2009).

Dog Meat, Domestication, and Special Ethical Considerations

In his popular book, *Eating Animals*, novelist and vegetarian Jonathan Safran Foer (2009) uses dogs as a device to expose the cognitive differences many people employ when thinking about those animals that are perceived as pets and those that are perceived as food. For Foer, this difference is one of visibility and invisibility, dogs are animals that those in Western cultures tend to think about as individuals – they have needs and wants and personalities – while other creatures, such as fish and cattle, are treated with detachment and cognitive distance. Ethicist Peter Singer (2009) also notes this cognitive distancing, a practice which he considers incompatible with his goal of treating all animals as independent sentient beings regardless of their species affiliation. Both of these treatments exploit the prevalence of the dog meat taboo to ask primary moral questions about eating meat: If other animals can be eaten, why not dogs? If dogs are given special status because of their amicable relationships with humans, why cannot the same exemption be given for pigs or chickens? As instructive as such questions can be in generating moral reflection on eating meat in general, however, the question of the differences between dogs and pigs or between any other dichotomy between a culturally accepted food species and nonfood species can be useful in its own right as well.

As described above, even when dog meat is viewed as culturally acceptable, it is not common for individual dogs to be considered both pets and food animals, except in times of extreme food crisis. The development of special breeds of

dogs for food and the common practice of exempting companion and other working dogs from the prospect of ending up on the dinner table. Harris (1998) notes that in the rare instances when food animals are treated as companions, such as pigs among certain groups in Papua New Guinea, their slaughter and consumption usually involves a ceremonial aspect – companion animals are ritually separated from their former roles before they become food. Frederick Simoons's survey of meat taboos (1994) catalogs a wide variety of animals, which fall into some broad general categories: animals that are seen as sacred, animals that are seen as dangerous, animals that are seen as polluted, and animals that are seen as useful in other ways. These categories are not always mutually exclusive nor are they universal for individual species. These categories, however, can be divided into two broader categories: animals that are dangerous to eat (for either physical or spiritual reasons) and animals that are inopportune to eat (because they provide some other benefit, from labor to companionship). According to Harris (1998), pets, despite their outward appearance of living idle lives, actually fulfill a number of social roles, working in essence as substitute human beings. Using dogs, especially pet dogs, as a model for how to think about and treat other species might not be an apt analogy, especially as their seeming life of luxury compared to a beef cattle appears to be more an artifact of the immense amount of "work" dogs do for their human hosts. If beef cattle have "one big job" at the end of their lives, pet dogs have an immensity of little jobs they perform from their birth to the grave, and in the cases of some especially beloved pets, even beyond. From this point of view, the question of whether or not animals are eaten does not do full justice to larger questions about humans benefiting from their largely involuntary work they do, both physical and emotional (Serpell 2009).

Summary

Dogs have been associated with humans for at least 15,000 years, as companions, guards,

hunting assistants, transportation, beasts of burden, and even food. Eating dog meat is common in the archaeological and historical record, with dog-eating communities found on every continent. Historically, dog meat was common among human groups that lacked other domesticated or wild protein sources. Dog meat continues to be eaten today, predominantly in East and Southeast Asia, with more isolated instances elsewhere. When dogs are raised for meat, they are usually treated differently than dogs raised for work or companionship, even within the same society. A taboo against dog meat is also common, perhaps deriving from diseases associated with eating dog meat or from the common use of dogs in other social roles that are seen as more valuable than their use as food animals. The globalization of cultures with the dog meat taboo has made it common in the modern era, and those countries and cultures that continue to eat dog meat are often treated with derision and castigation by animal rights activists and others that adhere to the dog meat taboo. In some places, such as Yulin, China, the outcry against dog meat has become a rallying point for those who wish to assert their cultural independence and autonomy. Similarly, efforts to ban dog meat in countries with historical consumption often result in the creation of a black market rather than genuine elimination of the practice. The practice of eating dogs is often used, especially in non-dog-eating cultures, as a loaded question to spur on discussions of the moral status of eating meat. In addition, the special role of dogs in human society open wider questions about the exploitation of animals in general, both as source of food and involuntary servants of human wishes.

Introduction

The agriculture of Eastern Europe is very diverse in terms of agroclimatic and socioeconomic conditions, cultural heritage, and historical context. There is, however, one common and unique factor

that brings this wide and diverse set of countries and agricultural settings into focus – the historical interface between their agricultural production systems and the Soviet sphere of influence between WWII and December 1991, when the USSR officially dissolved. Even though the longer history of this region includes many interactions among these countries, including wars, changing political regimes, and widely shifting borders, the focus of this entry is on the common socialist heritage and differing paths in the transition from the Soviet period to the present day. Specifically, we consider the issues, choices, and strategies associated with implementation of post-Soviet land reforms and transformation of collectivized and state-owned farms in these countries. As shown, the ethical issues such reforms created relate to the questions regarding the equitable distribution of resources. The discussion of land reform and farm restructuring includes such components as privatization and allocation strategies for the transferability of land and other farm assets. This entry also highlights future trends and unsolved problems in the region related to the structure of farming and performance of agricultural systems.

The countries included for consideration in this entry were either part of the Soviet Union or came under its influence following WWII (Fig. 1). The territory of former East Germany is not included, because it was unified with Germany in 1990. The specific countries consist of:

East European Agriculture, Fig. 1 Eastern European countries under the Soviet influence

1. Western countries of the Commonwealth of Independent States (CIS): Belarus, Moldova, Russian Federation, and Ukraine
2. Western Balkans: Albania, Bosnia and Herzegovina, former Yugoslav Republic of Macedonia (FYROM), Republic of Kosovo (Kosovo under UNSCR 1244), Montenegro, and Serbia
3. New member states of the EU: Bulgaria, Croatia (as of July 1, 2013), Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, Slovak Republic, and Slovenia

Implications of the Common Soviet Heritage

The Soviet approach to agriculture, which was centered around collectivization of land and other farm assets, heavily influenced the structure

of agriculture in the region for nearly 50 years. Despite this universal influence, East European countries differed in how they implemented collectivist principles. These differences were often the result of varying pre-Soviet agricultural structures, which also influenced and shaped the post-Soviet agricultural transitions. For example, among USSR countries, the three Baltic countries (Estonia, Latvia, Lithuania) had a growing private and individual farming sector during the interwar period and clear property rights that could be the basis for land restitution, while Ukraine had no such basis for post-Soviet farm restructuring. Among Central and East European countries, the Yugoslav Republic did not experience any significant farm collectivization and Poland collectivized but then rapidly decollectivized, whereas most other nations did experience enduring collectivization. Finally, Belarus is alone among all these countries in terms of preserving much of the

farming structure of the Soviet period and seeing very little change in its political system as well. In this entry such differences among the countries in the region will be briefly discussed, and their role in shaping transition processes in agriculture will be explored.

At the core of the Soviet agricultural model was the forceful collectivization of the peasants' land and other farm assets that started in the early 1930s in the Northern Caucasus, Volga, and Siberian regions of Russia and Ukraine (Wegren 1998). By the early 1960s the collectivization was completed throughout most of Eastern Europe, except for Poland and Yugoslavia, whose agriculture remained largely based on small-scale farming throughout the Soviet period. Nevertheless, these individual farming systems still operated under central (State Plan) control of the economy even in Poland and Yugoslavia, and the structure of farming was essentially frozen in place, while individual farms in nearby Western European countries were evolving in size and structure in response to changing policy and market conditions.

As a result of collectivization, a system of large farms was created. In the 1980s, an average farm in the USSR had over 4000 ha of sown land, which was one to two magnitudes larger than the farms in the market economies with comparable agricultural resources (Lerman et al. 2004). Moscow saw industrialization and mechanization of agriculture as a major way of agricultural development of the Soviet nations. It was also easier for the state to control the production and distribution on fewer large farms rather than on numerous small ones, even though there still were more than 50,000 state and collective farms in 1988.

There were two types of large farms – state farms (*sovkhoz*) and collective farms (*kolkhoz*). In case of the state farms, land and all the production assets belonged to the state. Its employees were considered state employees who received monthly salaries and wages, similar to industrial enterprises. Collective farms, on the other hand, presupposed that, while the land was owned by the state, the productive assets were jointly owned by the members of the farm. The workers from the farm were compensated through the distribution

of the farm earnings instead of state-issued salaries (Lerman et al. 2004). Starting in 1966, collective farm employees were to receive regular wages and became eligible for state-provided welfare benefits. In reality, much of their remuneration was in-kind rather than monetary in the 1960s and into the 1970s. Over time the differences between two types of farms were often indistinct as the government's social and agrarian policies increased collective farmers' incomes and improved the level of mechanization for these farms. If, for example, the earnings of a collective farm were insufficient to pay planned wage to its workers, the state would provide the missing funds from the budget. It was also common for especially successful collective farms to reregister as a state farm.

A common feature of most state and collective farms was that families of workers had personal plots (household plots or *lichnoe podsobnoe khoziaistvo*), on which families could grow vegetables, potatoes, or fruits and raise a few animals, primarily for their own use. They often relied heavily on inputs and machinery services of the main farm where they were employed. These subsidiary plots, as they were also sometimes called, became more important in the post-Soviet transition, because they were the first ones in line for privatization.

Another distinctive feature of the Soviet agricultural model was central control by the state of all aspects of farm production, wholesale prices, and retail prices of food. Both input supply channels and output markets, including food storage, processing, distribution, and sale, were controlled by the central authorities who also set the production targets. The state also had a monopoly over all agricultural finances, credit, and banking.

During the 1980s, agriculture constituted a significant share in the economies of the Eastern European countries. As is highlighted in Table 1, during this time, the agricultural sector on average accounted for almost one-fifth of the GDP in the Soviet bloc, with the largest share of agriculture value added being in Albania, Belarus, Moldova, Ukraine, and two Baltic countries (Estonia and Lithuania). Rural population on average accounted for 44% of the population, while

^a1992 estimate

agricultural employment constituted 23% of the total employment (compared to only 13% in 2010).

Because the economies of Eastern European countries were heavily dependent on agriculture, agricultural reforms, especially privatization and farm restructuring, constituted some of the main components in the transition programs of the former socialist countries. Nevertheless, although the privatization of agricultural land and other farm assets and the restructuring of traditional collective and state farms were widespread, the methods adopted to implement these policies fell into different patterns. The land privatization was usually dominated by either restitution to former owners or by distribution to farm workers. The restructuring was focused either on creating family farms or on creating other forms of

market-oriented organizations, such as cooperatives of owners of agricultural assets, joint-stock companies, limited-liability companies, or partnerships. Depending on the methods of privatization and government policies of restructuring, different farm structures emerged in different transition countries. Table 2 summarizes the major differences in land distribution and land markets functioning in the countries of interest.

After more than 20 years of transition, all of the countries that were under the Soviet influence, except Belarus, were successful in the transfer of the property rights on land and other farm assets to private owners. In Belarus private ownership of land was limited to personal plots only; most of the land resources in the country remain state owned. However, in a number of countries, there are still substantial restrictions to the land market

functioning. In Ukraine, for example, a moratorium on purchase and sale of agricultural land has been repeatedly extended since 2002.

Post-USSR Patterns of Agricultural Transition

The countries in Eastern Europe can be divided into four broad categories, based on the type of land distribution and on resulting farm structure: (1) countries with land redistributed to the workers and predominantly corporate farming (Moldova, Russia, and Ukraine), (2) countries with land restituted to the former owners and predominantly corporate farming (Czech Republic and Slovak Republic), (3) countries with land restituted or compensated to the former owners

and a mixed structure of individual and corporate farming (Estonia, Latvia, Lithuania, Albania, Bulgaria, Romania, Hungary), and (4) countries where individual farming was preserved during the socialist era, and, thus, no significant land distribution took place after 1990s (Poland, Croatia, Macedonia, Montenegro, Slovenia, Serbia, Bosnia and Herzegovina). Albania and Belarus constitute unique cases. After the collapse of the Soviet Union, collective farms in Albania were disbanded and land was distributed to the former workers, but unlike the case of Western CIS countries, small farms predominated in the farm structure of the country since then. In Belarus private ownership on the land was only extended to the personal (household) plots, while up to 90% of agricultural land remained in the state and is operated by the large Soviet-style farms.

Land Distribution and Predominantly Corporate Farming (the Russian Federation, Ukraine, Moldova)

Before the creation of the Soviet Union, Western CIS countries did not have a widespread culture of family farms. Therefore, after the collapse of the USSR, the new governments of these countries followed the path of redistributing land to the workers of the state and collective farms rather than restituting it to the former owners. New landowners were first issued paper certificates of entitlement, which were later converted into physical land plots if certain conditions were met, allowing owners to rent out, sell, or form individual farms. Land was not registered to “households” but to individuals, either as joint ownership or single owner.

Despite the distribution of land to individual farms, the transition to small-scale family agriculture in Russia, Ukraine, and Moldova has varied greatly and the majority of agricultural land is still controlled by large corporate farms. The structure and significance of such farms, however, differ by country. For example, Russia and Ukraine have become a home to mega-sized farms (often larger than 100,000 ha), called agriholdings, which are often vertically integrated with processors and/or exporters. The majority of agriholdings have been formed in the grain sector, while some of them function in the oilseed, sugar, and dairy sectors. Some farms have managed to attract financing through IPO and borrowing from private investors or European Bank for Reconstruction and Development.

There are several reasons for the existence of agriholdings. Among them are vast availability of relatively cheap fertile land, small-scale landowners with little bargaining power over rental terms, poorly functioning credit markets, sufficient level of infrastructure development, access to world markets, productive and relatively cheap labor, and increasing commodity prices as a promise of higher profits. However, the major reason for their emergence as a unique phenomenon to the post-USSR (rather than Western) countries is the underdeveloped institutional and legislative conditions of the transition economies that allow for large capital accumulation.

Existence of such gigantic farms has both its benefits and risks; as a result, agriholdings are currently in the center of policy debate both in Ukraine and Russia. The major benefit of agriholdings is that they attract a large amount of investment in the agribusiness sector both from domestic and international investors. Additionally, the economies of scale of agriholdings allow them to decrease the cost and increase the efficiency of production, while the extent of their integration allows for the fast and smooth product movement from a farm to an exporter or domestic user.

The main risk is the disconnect between agriholdings and the rural areas where they operate. First, they displace significant numbers of agricultural workers, which reduces employment and incomes in the rural areas. Also, the major headquarters of such holdings are usually located in the larger cities and not in the areas where the production takes place. Therefore, agriholdings pay taxes to the cities, which, in turn, decreases the stream of financing to the rural territories. This results in lower levels of financing of infrastructure and public goods provision in the rural areas of Russia and Ukraine. Another risk is the tendency of agriholdings to engage in monoculture practices that lead to deterioration of land quality and other environmental externalities.

Land Restitution and Predominantly Corporate Farming (the Czech Republic, Slovak Republic)

Prior to WWI, Czechoslovakian agriculture was characterized by large estates. Between 1918 and 1945 before the Communist party seized power in the country, some attempts of redistribution of land to the Czech and Slovak peasants took place. However, major redistribution happened during the Soviet era. Between 1945 and 1948, the pro-communist government instituted a three-stage land reform that resulted in 4.2 million ha of land (both agricultural and nonagricultural) being confiscated from large owners. The upper limit on the size plot was set at 50 ha. Once the land was redistributed among the peasants, the second (collectivization) stage of the reform began. It implemented several strategies to incentivize farmers to participate in cooperatives. For

example, individual farmers were discriminated against when obtaining machinery for their farms. Sometimes the government officials would take a more direct approach by expropriating the land of the largest farmer in the village or forcing him/her to transfer land to the collective use. The major collectivization in Czechoslovakia happened during the 1950s (Swinnen and Rozelle 2006). By 1985, 63.5% of the land in the republic was owned by the collective farms, 30.4% by state farms, and the rest remained in private property.

Following the 1990s, new legal regulations with regard to land reform in the country were implemented in Czechoslovakia, which in 1993 split into the Czech Republic and Slovak Republic. According to the new legislation, land-owners could claim back their land which had been taken away during socialism. At first, the land reform presupposed imposing a limit on the claims by the former owners to 150 ha of agricultural land and later 250 ha of land, but in 1992 such limits were abolished. This resulted in non-egalitarian distribution of land in private ownership. As an example, after the land reform, a small group of Czech farmers owned 55% of the total privately owned farm land in the country (Swinnen and Rozelle 2006).

Land Restitution or Compensation to Former Owners and a Mixed Structure of Individual and Corporate Farming (Estonia, Latvia, Lithuania, Bulgaria, Romania, Hungary)

With regard to collectivization, Bulgaria was the first country to achieve full collectivization among the current EU new member states (NMS), which was not the case for Hungary or Romania. Even towards the end of the Soviet rule, both countries had a relatively large share of private agriculture, and their agricultural structure could be characterized as a symbiosis between small- and large-scale farms. The Baltic countries were part of the USSR and, therefore, fell under the collectivization orders from Moscow. By the end of 1950s, less than 10% of the family farms escaped collectivization in the Baltics (Meyers and Kazlauskiene 1998). However, since family farming was predominant in the agricultural structure of the Baltic countries before the Soviet rule, the transition

began with a priority to restore family-based agriculture through land restitution to the former owners.

After the fall of the communist regimes, the majority of agricultural land in the countries that are included in this category was redistributed to private farmers who used it to form family farms. However, there are still differences among these countries in terms of both collectivization processes and land reform implementation. For example, in Hungary, land was distributed both via compensation to former owners and land allocation to the workers of the state and collective farms. This was not the case for the Baltic countries, Romania, or Bulgaria, which only restituted collective land to former owners or descendants of the owners.

Preserved Individual Farms During Central Planning (Poland, Croatia, Macedonia, Montenegro, Slovenia, Serbia, Bosnia and Herzegovina)

Poland and the Socialist Federal Republic of Yugoslavia were two countries in which agriculture was never fully collectivized. For example, in both Poland and Slovenia, private agriculture accounted for 80% of arable land as of 1975 (Mathijs 1997). However, central planning was still introduced into agricultural development of these countries via limitations imposed on the private property rights on agricultural land and on the functioning of input and output markets.

Since individual farms predominated during communist times, after the 1990s the privatization of agricultural land was not as much of an issue as it was in other former socialist countries. The main transition process consisted of restitution of previously nationalized land used by the state farms to the original owners or their legal descendants.

Albania (Land Distribution and Predominantly Individual Farming)

Before WWII, more than 60% of land in Albania was cultivated by medium- and smallholdings. At the beginning of the communist era in the country, the expropriation was targeted towards large land-owners or those owners who used hired labor.

Such land was confiscated and transferred to landless Albanians or farmers who owned less than 5 ha of land. The expropriation stage of the reform was followed by a collectivization process. By the early 1960s, most of the family farms were part of either collective or state farms.

After the collapse of the communist regime in Albania, its government followed the path of the Western CIS countries with regard to land reform. Within a year and a half, all the land that belonged to the state and collective farms was distributed among former workers of such farms, who in turn started family farms. As a result, 700,000 ha of arable land was distributed among 500,000 families, with an average plot size of about 1.5 ha per family.

Future Trends and Unsolved Problems

Currently, agriculture constitutes a much smaller share in the economies of the Eastern European region than it did during Soviet times. During the past 20 years, the agricultural index in the region that is calculated as a simple average of the share of rural population (percentage of total population), share of agricultural employment (percentage of total employment), and agricultural value added in GDP (percentage of total GDP) has decreased on average by 33%. This is a natural path of transition for dynamic economies, but in this region it was accelerated by the removal of high levels of agricultural support after the collapse of the USSR. Nevertheless, agricultural issues are still at the center of policy debate across these countries.

The future trends in the agricultural development of the region could be centered around the stage of accession of the post-Soviet countries to the European Union. Here one can differentiate among those countries that are already members of the EU (new members states), those countries that are recognized as official candidates to the EU (Republic of Macedonia, Montenegro, and Serbia) or potential candidate countries (Albania, Bosnia and Herzegovina, and Republic of Kosovo), and those countries that are currently not on the enlargement agenda of the EU (Western CIS countries).

With regard to the agricultural reforms, the accession process to the EU is important for two reasons. First, in order to complete the official accession process, these countries have to implement laws and regulations in the *acquis communautaire*, which involves the adoption of the common policies and regulations of the Union, which, *inter alia*, improve functioning of the land markets. In this respect, new member states of the EU are in better shape than the countries in Western Balkans or Western CIS countries, since they have shown the most progress in the region with creating an efficient system of private property on land and land transferability. Second, accession to the EU significantly increased support for agricultural and rural development and also put pressure on farms and the whole marketing chain to be more competitive in agricultural markets. This assistance and market competition has improved the efficiency of agricultural markets.

Evidence (Table 2) shows that the NMS countries have the lowest level of land market restrictions, while Western CIS countries are still the most restricted ones in this regard. More specifically, according to the World Bank's land reform index of 2005, Western Balkan countries (except for Bosnia and Herzegovina) score on average at 7.2 out of 10. For the Western CIS countries, the average is equal to 4.9. These numbers refer not only to the state of land reform but also to policy environment, privatization processes, rural financial systems, and institutional framework (Mizik 2009).

Summary

This entry deals with the issues, choices, and strategies associated with the implementation of land reforms and transformation of collectivized and state-owned farms in the post-Soviet countries of Eastern Europe. The wide variety of paths that countries have taken in transition from state ownership and central planning to private ownership and market-driven processes do not reveal that one path is far better than another, but it generally shows that those countries that delayed and overly restricted adjustment processes are

lagging behind those that made the transition earlier and faster.

E

Introduction

Ample evidence exists on the negative influence on health of eating a diet high in energy, saturated fat, and salt and the onset of diabetes, cardiovascular, and malignant diseases (for an overview, see WHO 2004). The rising problem of obesity fuels the efforts of health promoters, policy makers, the food industry, and other experts concerned with nutrition communication to promote convenient healthful eating. Despite these efforts, promoting healthful eating remains a challenge (see ► [“Obesity and Consumer Choice”](#)).

At present, two contradictory trends emerge in nutrition promotion. On the one hand, decades of efforts have created awareness and understanding of eating for health, to eat a variety of food, more fruits, vegetables, and fish and avoid too much fatty and sugary food, calories, and salt, and have also created the intention to do so in practice. At the environmental level, great efforts have been put into “making the healthy choice the easy choice.” On the other hand, studies show that, in the Netherlands as well as in other countries, most consumers eat less fruit and vegetables and more products high in energy, saturated fat, and sugar than recommended. This latter type of dietary intake is indicated as one of the main causes of the increasing prevalence of obesity and consequent rise in adult onset of diabetes, nowadays a major public health concern in the Netherlands, as well as globally.

Apparently, knowing what to eat for health is not put into practice by many people. New

Eating

- [Gender Norms and Food Behavior](#)

strategies, therefore, have to be considered to ensure that consumers direct their eating practices toward health.

This entry discusses firstly the current biomedical-oriented strategy of specifying nutritional recommendations on why, how, and what to eat to remain in good health (2). Then, the mismatches between this approach and the way people themselves deal with food and health in their everyday lives are presented (3) and discussed in relation to ethical considerations (4). The next section introduces the salutogenic perspective (5) and the evidence regarding its value for application to the promotion of healthier eating practices (6). The last part of this entry discusses implications and examples of using this perspective for nutrition research and promotion (7) and conclusions (8).

Existing Efforts: Nutritional Specification

Nutritional research is increasingly capable of identifying the relation between specific nutrients and physical health. The insights are translated into guidelines for healthful eating and communicated to consumers through educational and marketing efforts. The rising problem of obesity fuels the efforts of health promoters, policy makers, the food industry, and other experts concerned with nutrition communication to facilitate convenient healthful eating.

The further specification of advice on why, what, and how to eat for physical health is fuelled by three developments. Firstly, behavioral research supports the idea that specific advice is more successful than general advice in motivating healthful eating because individuals view it as more personally relevant (Eyles and Mhurchu 2009). This so-called tailored advice provides individuals with highly specific information on individual health risks and benefits of their current eating habits and the desirable changes (see ► “Food Risk Communication”). In addition, rapid developments in interactive computer technology (ICT), especially the Internet, allow for the provision of tailored advice on a larger scale than possible through face-to-face consults

(Broekhuizen et al. 2012). A third development is that of nutrigenomics research. This innovative discipline of nutritional research studies the interaction between food, genes, and health at the molecular level. A genetic test for vulnerability to diet-related disease, such as cardiovascular disease, could be added to a personal risk assessment, one that is currently comprised of indicators such as body mass index and blood cholesterol (German et al. 2005).

In addition to individually tailored advice, making healthy choices is facilitated by a growing variety of convenient, tasty, and healthful foods and meals available to consumers. These may facilitate uncomplicated healthful and pleasurable food choice. And, if needed, consumers can buy functional foods, in the form of health-claim-carrying products or natural foods that offer convenient, instant compensation for potential damage done to health (Bouwman et al. 2009; see ► “Functional Foods”).

Nutrition Research and Everyday Eating as a Social Practice

The key idea that drives a lot of nutrition research and promotion is that eating for attaining or maintaining good individual physical health is a central goal in life. This biomedical notion of health drives the search in nutritional studies for a better understanding of the risks and benefits of certain nutrients for physical health. It is related to that of “healthism,” a concept introduced by Crawford (1980) to describe a new form of health consciousness that refers to a preoccupation with personal health as the primary focus for the achievement of health and well-being. Health behavior thereby became the paradigm for good living.

The studies based on this biomedical approach orient toward pathogenesis, the study of disease origins and causes. It starts by considering disease and infirmity and then works retrospectively to determine how individuals can avoid, manage, and/or eliminate that disease or infirmity. This risk-oriented, pathogenic view underlies the search in nutritional research and promotion for

nutrients, foods, and meals that prevent, treat, or manage diet-related diseases.

A parallel can be drawn between nutritional research and behavioral food research, the research areas that provide the scientific basis for nutrition promotion strategies. Both areas study how interactions between humans and their social and cultural context impact physical health. The areas also share the difficulties involved in exploring contextual variables that often cannot be controlled in research studies (Fischer 2006). If humans are studied without considering contextual influences, the validity of the research results for everyday life situations is limited. This applies to nutritional research, where issues about contextual influences are threefold: (1) limitations of studying single nutrients while people consume food products, (2) studying specific food products while people consume diets composed of many foods, and (3) studying diets without considering other lifestyle components. This perspective causes a gap between healthy eating guidelines (e.g., eat polyunsaturated fats and avoid sugar) and concrete action rules for real-life eating practices.

The review of the literature on health behavior change and health communication on this aspect of Bouwman and van Woerkum (2012) indicates mismatches between the focus on physical health in nutrition promotion and consumers' own view.

Firstly, that healthful eating is not solely a matter of conscious personal choices for the benefit of maintaining or attaining physical health. Studies show that eating involves other functions such as taste, convenience, costs, moral concerns, and the maintenance of relationships (Sobal et al. 2006) that often take precedence over biomedical health. Scrinis (2008) argues that the narrow focus on physical health, so-called nutritionism, may have limited value in everyday life (see ► [“Medicalization of Eating and Feeding”](#)). The scant attention paid to the social and cultural circumstances in which attitudes or intentions are formed in the dominant, cognitive perspective on health behavior more generally is widely addressed in literature (Fischer 2006; Green 2006).

The second issue concerns the absence of the social dimension of eating in nutritional

guidelines. Decisions and actions regarding food habits are embedded in a range of other social activities. Following nutritional guidelines in daily life is therefore not a matter of course (cf. van Woerkum and Bouwman 2012). Yet, nutritional guidelines are oriented toward the physical side of health and the concurrent denial of the social embeddedness of food and health behavior and thus seem to ignore that aspect. Food is often shared with others and provides opportunities for making social contacts. Within these social interactions, it may function as a marker of culture and as an expression of affection, attachment, or identity (see ► [“You Are What You Eat”](#)). Apart from being a social activity in itself, eating behavior is also influenced by the broader social context. This social environment has been proven influential in stimulating or inhibiting consumers' capacity to eat more healthfully. A recent review of qualitative studies confirms that healthy eating reflects people's personal, social, and cultural experiences, as well as their environment (Bisogni et al. 2012).

A third issue concerns the increasing specificity, and thereby the complexity, of what to eat and what not to eat for the benefit of health. Healthful eating requires a well-organized life, but many consumers are unable to achieve this. Dealing with complexity seems to become more important than eating in accord with nutritional guidelines itself. This complexity is only partly taken care of by health promoters, policy makers, the food industry, and other experts in nutrition communication who facilitate convenient, healthful eating. For instance, a growing variety of convenient, tasty, and healthful foods and meals are available to consumers. These may facilitate uncomplicated healthful and pleasurable food choice. And, if needed, consumers can buy functional foods, in the form of health-claim-carrying products or natural foods that offer convenient, instant compensation for potential damage done to health. It may however lead to the idea that critical thinking by individuals on how to organize healthful eating in everyday life can be handed over to experts. As a consequence, consumers themselves may deal with healthful eating as uncomplicated and unproblematic, as not requiring thoughtful

consideration, because someone else is already taking care of it (Bouwman et al. 2009).

Ethical Considerations

Besides questions regarding the everyday relevance and applicability of biomedical-informed nutrition promotion strategies, ethical issues arise as well. A first question is whether the biomedical, pathogenic route toward specification sufficiently addresses autonomy and, hence, will indeed enable healthier eating practices. The second question relates to the increasing specificity and whether this route will exclude those who are in most need for support.

The first issue concerns the tension between the expert-driven nature of the current approach toward food and health and autonomy, the capacity to self-govern and self-control, and being able to act in an independent manner in relation to eating. Health promotion and, hence, nutrition promotion aim for the human rights value of enabling people to lead an autonomous, active, and productive life, a “good life” or quality of life (WHO 1986). Yet, the expert-driven nature of the current food arena reduces the need for self-governance and self-control and hence autonomy in relation to food choice. It can be questioned who is in the drivers’ seat in the food-health arena, where complex nutritional information is simplified by experts and presented in claims, logos, and guidelines on health and sustainability. “You are what you are told to eat” seems to replace “You are what you eat,” signaling distance between people and the way food is produced and “served” in television programs and advertisements and on the food itself.

The availability of specified nutrition advice may also induce societal attribution of extended individual responsibility for one’s health (Korthals 2011). It is however questionable whether the singular focus on attaining biomedical health (Nutritionism) enables increased accountability (Nordström et al. 2013). Enabling the “good life” requires an integration of social and spiritual life ambitions and actions, especially in relation to food. Without consideration of these

values, the biomedical route may compromise rather than support autonomy and healthier eating practices (see ► “Medicalization of Eating and Feeding”).

The second ethical issue concerns that provision of tailored advice on why, what, and how to eat for health presupposes a self-conscious consumer, willing and capable of finding, understanding, and applying the information. It requires a certain level of “nutritional intelligence.” People who do not accomplish this level may ignore, discard, or misinterpret the information. Similar to other health-related issues, unhealthy eating and its consequences are more prevalent among groups with low socioeconomic status. Nutrition education has shown to be relatively ineffective among lower-income groups (Robertson et al. 2007). Further specification and hence complicating information may therefore not reduce yet increase societal inequalities.

The Salutogenic Perspective on Health

The above sketched issues which result from the dominant role of the biomedical route in nutrition promotion can be addressed by adding a complementary, context-sensitive route. Salutogenesis – a theoretical perspective on health – offers an excellent starting point. Antonovsky’s salutogenic approach is centralized around the question “what creates health?” It targets the search for ways to create, enhance, and improve physical, mental, and social well-being. A key difference with the biomedical perspective is that it assumes health-related practices – such as eating for physical health – as a resource for living rather than a central goal of life (Antonovsky 1987). Healthful eating, together with other biological, material, and psychosocial resources, makes it easier for people to perceive their lives as consistent, structured, and understandable. These resources foster repeated life experiences which help to view the world as “making sense,” cognitively, instrumentally, and emotionally. Antonovsky uses here the metaphor of “stimuli bombarding one from the inner and outer environments are perceived as information rather than noise.”

Out of this way of thinking emerged the sense of coherence (SOC) construct. This orientation perceives the world, on a continuum, as comprehensible, manageable, and meaningful. The strength of one's SOC is a crucial factor in facilitating the movement toward health. Confronted with a stressor, a person with a strong SOC will be motivated to cope (meaningfulness), believe that the challenge is understood (comprehensibility), and believe that resources to cope are available (manageability). Comprehensibility represents the cognitive component, manageability the instrumental or behavioral component, and meaningfulness the motivational component (Lindstrom and Eriksson 2006).

Life experiences that lead to a strong SOC allow one to reach out in any given situation and apply the resources appropriate to that stressor. Three kinds of life experiences shape the strength of one's SOC: consistency, underload-overload balance, and participation in socially valued decision making. The extent of such experiences is formed by one's position in the social structure and by one's culture – e.g., work and family life.

Salutogenesis and Healthy Eating

Antonovsky developed a scale to measure the strength of the SOC, called the Orientation to Life Questionnaire, which included the SOC-29 and a shorter form, the SOC-13 – comprising of 13 questions on meaningfulness, comprehensibility, and manageability. Since these SOC scales were originally devised by Antonovsky in the 1980s, they have been translated into at least 33 languages in 32 countries with at least 15 different modified versions of the questionnaire available. These scales measure the strength of the three traits which compromise the SOC: meaningfulness, comprehensibility, and manageability. These SOC scales have been found to be highly reliable, valid, and cross-culturally applicable instruments to gauge how people cope with stressful situations and as a result stay healthy (Eriksson and Lindström 2005).

In an extensive systematic review, Eriksson and Lindström (2006) found that a high SOC

score was strongly associated with a better perceived physical and mental health and it has a main, moderating, and mediating role in the explanation of positive health. Several studies have also proposed that a strong SOC is associated with healthier eating patterns and lifestyle choices than those with a weaker SOC. Lindmark et al. (2005) found in a cross-sectional study of Swedish adults that both men and women with a high SOC score reported higher intake of healthier food choices such as vegetables and whole grains. They further found that those with lower SOC scores reported higher intakes of unhealthier food choices such as pizza, French fries, and hamburgers. Moreover, research from a population-based cohort study in the United Kingdom found that men and women with a strong SOC were less likely to smoke cigarettes; less likely to be physically inactive; reported higher intake of fruits, vegetables, and fiber; and had a 20% reduced risk of all-cause mortality than those with a lower SOC, independent of social class and education level (Wainwright et al. 2007). Ray et al. (2009) further found that a strong parental SOC was associated with their children having more regular child eating patterns, lower intake of energy-dense foods, and higher intake of nutrient-rich foods. Their evidence further suggested that parent's SOC and children's intake of nutrient-rich foods were mediated by factors from the social and physical context such as providing access to fruits and vegetables at home, having better awareness of recommendations on healthy eating, acting as a role model for their child by eating fruits and vegetables, and eating regular meals together as a family.

Salutogenic research goes beyond only measuring SOC and its association with health and lifestyle behaviors. As Lindström and Eriksson described, salutogenesis is “much more than only the measurement of the Sense of Coherence, it is a much broader concept focusing on resources, competencies, abilities; assessed on different levels, the individual, the group, families and also societies, of which the concept of resilience is one of these assets to health that falls under the salutogenic umbrella” (Lindström and Eriksson 2010). Resilience can be described as a

positive capacity to cope with stress and adversity. Qualities of resilience such as flexibility, resourcefulness, and coping with adversities are very similar to GRRs which create the prerequisites for developing a strong SOC as described by Antonovsky. Further, resilience is just like salutogenesis in that it is not a trait, but rather a dynamic process that illustrates how the availability and use of resources can be used to promote well-being (salutogenic) or protect people from adversities (resilience) to set people on the continuum of positive health.

In the past, the concept of resilience had been mostly applied within only child development, mental health, and psychology; however in recent years the concept has been applied to a variety of topics. Australian researchers have begun to apply the concept to study the phenomenon of “obesity resilience” among populations with high levels of health disparities. This research has suggested that characteristics such as perceived social support from family and friends for healthy eating and physical activity, perceived self-control for healthy eating, self-efficacy for regulating eating and physical activity, social participation, and neighborhood access to healthy foods all explained variations in BMI in women living in disadvantaged neighborhoods (Ball et al. 2012). Moreover, Williams et al. (2011) identified personal, social, and environmental factors that promote healthy eating and healthy weight among families from economically disadvantaged neighborhoods in Australia. These included parental control, moderation and support for healthy eating, parental role modeling, and limiting access to unhealthy foods. American researchers have also recently begun to examine the obesity resilience phenomenon. Lim et al. (2011) found that among families from deprived neighborhoods in urban Detroit, a higher parental capacity for resilience was associated with healthy weight maintenance and lower soft drink consumption in their 3 to 5-year-old children over a 4-year follow-up period.

In sum, the salutogenic research paradigm strives to ultimately answer the question “what creates health” rather than “what causes disease” and, hereby, complements the biomedical route in

multiple ways. The salutogenic view toward health complements the biomedical route by adding the everyday life dimension where people strive not only to avoid disease yet also for quality – “goodness” – in life. People need to be aware of not only risks that keep them from achieving good health but also how they can use resources within and outside themselves to guide them successfully toward positive health. It includes all aspects of health, being in line with the way people themselves experience health: as resulting from an interplay between bodily, mental, social, and spiritual well-being. It is embedded in the social context; it studies the dynamics between people and environment and how health develops from this interaction – or not. It aims to identify the patterns and mechanisms underlying health processes, rather than factors bound to people, as is characteristic to biomedical-oriented research. Disjointedly studying and enacting upon people and context may be easier but does not do justice to reality. Society can be rich in resources; the outcome depends on how people make sense, interpret, and give meaning to these resources in relation to health.

Implications for Research and Practice

In summary, the evidence emerging from salutogenic research suggests that a higher SOC score is associated with better perceived physical and mental health and it has a main, moderating, and mediating role in positive health outcomes. Findings from the salutogenic literature suggest that those with a higher SOC make healthier food choices, eat less energy-dense foods, have healthier physical activity patterns, and tend not to be smokers. Such research has been important to gain initial insight into the resources that promote healthful eating and resilience to obesity at the individual, family, and community levels. However, we have only just begun to scratch the surface. In-depth qualitative research has yet to be applied to study the mechanisms and patterns behind the phenomenon of eating well. In future research, it will be important to examine how healthy eaters adapt and utilize resources in

health-promoting ways despite such overwhelming influences of the “obesogenic” environment. For instance, what types of life experiences with healthy eating and lifestyle have shaped the development of a high SOC and resilience to obesity?

The use of the salutogenic perspective has several implications for research. The target groups are those who do manage to sustain in their intentions to eat healthfully and find out why they are doing well. The questions should centralize around the life experiences that have led to their strong SOC, their ability to cope with a “challenging” environment in relation to eating for health. With respect to eating, one can think of how they deal with the abundance of food, “seductive” marketing efforts, pricing strategies, as well as negative social norms – e.g., the health freak image mentioned above. What are the knowledge, tools, or skills, on a biomedical (as provided by existing nutrition advice), practical, as well as social level, required to effectively deal with these challenges in everyday life?

Secondly, research should not be limited to topics directly related to the food chain process of buying, preparing, and consuming food. Peoples’ other, interlinked ambitions and actions should be considered as well. The aim is to identify how eating for health is linked with other resources that contribute to health and well-being, for instance, experiencing nature, playing, or child rearing. In line with this, care farms, natural playgrounds, or city gardens may serve as excellent settings for promoting eating for health.

A third aspect is the question how the complexity that characterizes advice on why, how, and what to eat relates to the element of comprehensibility, the understanding of one’s environment. We propose that nutrition promotion, besides considering the impact of (un)healthful food choice on personal health, also includes other levels (from local to global) and domains linked with food (e.g., animal welfare and natural resource management).

The complex nature of eating advice may also hinder the opportunity for positive life experiences required to establish a strong SOC. As mentioned above, these life experiences should be

characterized by consistency, an underload-overload balance and participation in socially valued decision making. The fast changing insights on food-health relations may not provide for consistency. And the enormous attention paid to food-health may lead to an overload of information. The importance of the aspect of “participation” is widely recognized in health promotion and central to human rights. Yet, current nutrition promotion efforts insufficiently allow for active involvement of people themselves (Bouwman 2009). We therefore wish to emphasize the need for a change from expert-driven nutrition promotion toward a coevolutionary development process. In this process, people themselves are actively involved, issues and solutions can be exchanged between consumers and experts, and new ways to establish eating for health may be devised.

Summary

The biomedical specification route provides valuable insights on risk factors and strategies to avoid disease. Yet, its complex nature and distance to the everyday context of eating practices may limit the impact of nutrition promotion efforts and compromise the values of autonomy and health equity. Complementing this route with the salutogenic approach will be relevant for public health practice in developing interventions that enhance and develop personal, social, and environmental resources which foster healthy eating practices. Through coordinated action with relevant societal actors, findings could also be used to propose and develop “salutogenic” public health interventions which fit within current frameworks and policies. Furthermore, the research findings can help develop new tools for practitioners to assist people that are struggling with their weight in designing a “personalized health trajectory” that enables and empowers them to utilize personal, social, and physical resources for health. Most importantly, such action-oriented approaches form part of the solution and help people in accomplishing lifestyle changes in the context of their everyday lives (van Woerkum and Bouwman 2012).

It can be expected that salutogenic research findings will be highly valuable not only for practitioners but also for policy makers and industry. The knowledge gained from salutogenic research can be used to design more holistic, context-sensitive, and solution-oriented obesity and lifestyle-related policies, as well as develop socially driven technologies and devices which emphasize enabling and facilitating resources within people's social and physical contexts as a means to promote health and prevent obesity. Health promotion has a long tradition of arranging enabling contexts to mobilize human and material resources to promote and protect health.

This does not require a complete paradigm shift to using only salutogenic methods, rather that there should be more of a balance between pathogenic and salutogenic methods in obesity research. Introducing more salutogenic approaches to obesity research can complement the existing knowledge by identifying the "determinants of success" in those coping well with the obesogenic environment and comparing these to the established "determinants of failure" in people who struggle with overweight and obesity due to unhealthful dietary and lifestyle practices. By widening the research perspective to encompass both approaches, one can better understand how the complex interplay between physical, mental, social, and contextual factors can support the maintenance of a healthy weight and promote well-being. This understanding can ultimately aid science and practice in creating supportive and enabling social and physical contexts which promote healthy eating, lifestyle practices, obesity prevention, and overall health.

Christian eating, Commensality, Eucharist, Fasting, Fellowship meal, Holy Communion

Introduction

Eating in the Christian church affects and is affected by the surrounding culture of the time. This is evident today as well as in ancient Christian antiquity, the first centuries following the life of Jesus Christ. The mid-Medieval era (700–1000 C.E.) and the early Renaissance era (1400–1700 C.E.) which included reforms and transformation within the Christian church (like the Protestant Reformation) and the transformation of a commercial class where money superseded the importance of allegiances also had an impact on Christian practices of eating, both spiritually and socially. This entry reviews the history of Christian eating in ancient antiquity, the early Renaissance era, and from the eighteenth century in America up to the present time.

Ancient Antiquity

The institutionalized nature of the common (or communal) meal and its extraordinary social importance is embedded in culture. In the ancient Mediterranean region, communal meals were shared by all in the community, yet people were stratified into seating places based upon class. Matthias Klinghardt (2012a), a history scholar in Christian eating practices, states that the main or (meal) proper was typically followed by a drinking party called the symposium proper (*convivium*). The nature of this party transcended

the meal (Smith 2012). This meal structure provides necessary background for understanding Christian meals during the first two centuries of the Common Era (C.E.). These meals were not so much symbolic, as in sacramental, but rather actual meals involving the wider community. References to “bread” and “wine” refer to the two main parts of any communal meal, rather than to the sacramental aspect of a symbolic “token” meal, which first appears during the third century CE (Klinghardt 2012a).

Prior to the third century, Christian meals were like all meals in the Hellenistic-Roman world, a community meal in which the participants ate plentifully. There were generally more than one or two courses served in a meal or dinner (Klinghardt 1996). Meals included a wide variety of foods contingent upon who the host was or financial means and cultural backgrounds of those who dined. As different from today in the Mediterranean, meat and fish were regularly consumed only by the rich. Most people in the Greco-Roman era predominantly ate grains and vegetables (Klinghardt 2012a). K. Begere (1993) states that “Meals were saved as side dishes accompanied by cereal flat cakes or bread. The latter was indispensable for scooping up the side dishes, since silverware was unknown” (p. 77). Breaking bread by hand and handing out bread during Communion is not a uniquely Christian custom but rather the common indication by which any meal would begin. The structural distinction between the eating and the drinking parts of a meal implies that drinks were generally not served during the dinner (Klinghardt 2012a).

The ritual of libation, the pouring out of a drink as an offering to a deity, is an important feature of the meal in ancient Christian antiquity. The libation follows the main meal and indicates the opening of the symposium. This religious ceremony, which had varying forms, was well established. The practice of libation took place in religious and non-religious “secular” meals in the modern sense (Klinghardt 2012a). Consequently, any form of community within the context of a communal meal had some elementary features of religion: “The experience of community could not be

envisioned without some connection with the transcendent” (p. 11).

Libations are referenced in New Testament literature. In Jesus’ Last Supper, Mark 14:23 and Matthew 26:27 directly mention that Jesus had the disciples drink from the one cup he handed out; although Luke 22:20 clearly states that the cup “after dinner” was “poured out” (Klinghardt 2012b). Klinghardt (2012a) expresses that with the Last Supper accounts in Luke and 1 Corinthians 11, it is supposed by biblical scholars that at least part of the early Christian meal followed a similar practice of libation.

Recitation of a libation prayer was likely made by all in attendance. This prayer was in the form of a song, and conducting a prayer in unison was thought to give it further religious effect (ibid.). This practice involved much coordination which gave way to creating fixed formularies for such prayers (Klinghardt 1999). Among the popular prayers are the Thanksgiving prayer after the “full meal” in the Didache 10:2–6 (31) and the Mishnaic formularies for the prayers at the table or contained within the grace after dinner. Scholars generally believe that “the cup of blessing which we bless” from 1 Corinthians 10:16 applies to the libation cup and the coinciding prayer. The community concept attached to the ancient meal is responsible for other features of the meal. Hunt and Murray (1999) express that cooking in the Mediterranean region since the first centuries C.E. were based on cereals from wheat. Porridge, gruel, and later bread were common meals. All who dined commonly ate the same food and drank the same wine. They sang a *paean* (song of praise or triumph) in unison and gave their own contribution to the sympotic entertainment and sometimes to the provision of the food (as in a potluck party). This aspect of the meal was perhaps most contentious as rules for how the guests or participants at the meal were seated was challenged (Klinghardt 2012a).

Meals in the early Christian era allowed people living in the same social situations to have similar religious experiences. Personal acceptance and having a social place within the group was an important facet of community brought about by eating together. Religious experience from a meal

then came about through the intangible – feelings of grace (unconditional love from God), a sense of abundance, and the presence of justice. There was a kind of contravening experience that transcended the experience of routine life (*ibid.*).

The New Testament provides an important look into the early Christian banquet's characteristics. In 1 Corinthians 11:23–25, which is Paul's account of the Last Supper meal, the banquet of Jesus is presented as following the *deipnon* (banquet) symposium model. In this model, Jesus first pronounces a benediction over bread, and then, "After the *deipnon* he took the cup of wine" (*ibid.*, p. 24). Paul tells the story in the setting of a discussion about the meal of the Corinthian community, which he refers to as the "*deipnon* (banquet) of the Lord."

The Corinthian community and the extension of Paul's churches throughout the Eastern Mediterranean were following the Greek banquet for their community meal. New Testament readings portray that the Greek model would be prevalent. In addition, the Roman banquet model allowed the element of conversation (Roller 2006).

A common expression for the banquet as described in the above sections could be "festive joy" (Klinghardt 2012a). This refers to the central meaning of the meal as a time of enjoyment and celebration. In the philosophical discourse of the era, the concept of festive joy represented "pleasure," which then became a guide for proper behavior (or social obligation) at the banquet. In essence, proper behavior at the banquet increases the characteristic pleasure of festive joy of all who are present (Smith 2003).

Medieval Era and Early Renaissance Era

From the eight to the eleventh centuries, the European diet containing cereals increased in proportion from 1/3 to 3/4. Foods containing wheat were primary foodstuffs through the medieval era, and this moved northward with the increased adherence to Christianity. In colder climates, however, it was often too costly for most of the population and was associated with the higher classes. The focus on bread in religious rituals such as the

Eucharist gave bread more dignity among other foods, equal to that of olive oil and wine (Hunt and Murray 1999).

The Roman Catholic and Eastern Orthodox churches and their seasonal calendars had important impacts on eating practices. Eating meat was not allowed for a full third of the year for most Christians. Bridget Ann Henisch (1976) states that animal products like eggs and dairy (excluding fish) were commonly prohibited during Lent and fasting periods. In addition, it was routine for all church members to fast prior to taking the Eucharist. Fasting took place over a day's time, requiring total abstinence.

Both the Eastern and the Western churches established that banquets (or feasts) should be alternated with times of fasting. Fridays were fast days across Europe and were practiced on various other days and seasons including Lent and Advent (*ibid.*). The intention of fasting was to suppress the body and revive the soul, reminding the faster of Jesus Christ's sacrifice for humanity. The purpose was not to suggest that certain foods were unclean, but to provide a spiritual lesson in self-restraint through abstinence.

Most of the faithful honored the limitations of these religious food laws and commonly made penance when they defied them; there were also numerous ways of avoiding these rules.

As animal products were to be avoided during times of penance, practical concessions succeeded. The definition of fish products was open but portion sizes were reduced during restricted eating seasons. Moderate drinking and eating sweet foods were not prohibited. While Byzantine church leaders had a stringent approach to food laws, particularly preventing church ministers from following more desirable diets, the Western church was more permissive. Prohibiting eating meat over long periods was frustrating to people (*ibid.*).

Conversely, when the church celebrated feasts there was no lack of food. Nobles still dined with sophistication. In some cases, the extravagance was exceeded by Benedictine monasteries, which provided their diners with as many as 16 courses during certain feast days. Henisch

(1976) also mentions that exclusions from fasting were often made for a wide range of groups. Catholic monastery leaders addressed the concern of friars avoiding fasts with disapproval on moral grounds and emphasizing that non-meat meals were provided on fast days. Feasting, fasting, rituals, food laws, and social class all were intricate elements of an evolving tradition of food within the early Christian church. The eighteenth century on, explored in the next section, saw liturgical debates over Communion and the influence of practicality with the church's food traditions.

Eighteenth Century to Present

Sacramental Food

The sacred food of the Christian church lies in the sacrament of Holy Communion or the Eucharist. The act of receiving communion reflects closeness to God and marks inclusion in the faith community. Many churches consider their members to be members once they have communed at least once a year and have given an offering (e.g., monetary giving to the church) at least once a year. All Christians observe Communion as instituted by Jesus Christ and as an important part of their worship life. Many denominational theologies are distinct from one another as to how they view the bread and wine of communion as it relates to Jesus' body and blood and salvific sacrifice for humanity. The unity of the church in Jesus Christ is signified by the common communion cup where everyone partakes in drinking from the cup during Holy Communion.

Eating in this spiritual way has not been without its conflicts. In the 1800s, the American temperance movement had many churches considering just how they would use wine during the sacrament or if grape juice or another non-alcoholic drink could be used. This forced the church to embrace primitivism, which means that the only genuine practice for administering and receiving the sacrament was the original practice of when Jesus was instituting Communion. This primitivism meant that the correct celebration of the sacrament required alcoholic wine

(Aquinas 1947). Also, in the late 1800s, sanitation considerations came to the fore of whether germs could be easily passed by each person drinking from the common cup (Sack 2000). This issue placed laypeople, and especially physicians, against clergy and theologians as to understandings of how best to distribute the sacrament – drinking from the common cup, or having individually prepared small cups filled with wine, or pouring the wine into cups from the chalice at the time of Communion. By the early twentieth-century, individual communion cups had become common in use among American Protestant churches. The issue of sanitation also applied to the bread of Holy Communion, whether the bread should be cut into small cubes and whether it should be distributed by a worship assistant rather than passed around between church members.

The countercultural movements in America in the mid-twentieth century searched for spiritual life, for real experience, and for community but had minor interest in the traditions of the church (Sack 2000). As part of this, seeking togetherness at the Communion table during worship was an important theme in the worship life of the church, and observers stated that in partaking of the same cup and the same loaf, “we act out what we would like to be as church; we practiced eating as the Body of Christ so that we might become the Body of Christ” (Willimon 1998, p. 108). This countercultural search for community necessitated the church to review its Communion practices.

In the 1950s and 1960s, clergy and theological scholars participating in the liturgical reform movement wanted to change the practice of the Lord's Supper (Kirby 1969). Their movement frequently went against the beliefs of the laity, mostly regarding the individual common cup. In the Roman Catholic Church, the second Vatican Council (1962–1965) also designated changes in worship practices. The human immunodeficiency virus (HIV), the disease virus that causes AIDS, began quietly in the early 1980s, but by the middle of that decade, it was considered the country's foremost public health threat. Unavoidably, AIDS became an issue in the common cup debate in almost every denomination. Like the sanitation concerns of using the common cup in the late

nineteenth century, AIDS in the late twentieth century forced another discussion about ethical and theological implications of sharing the common cup next to practical and safety measures.

The last half of the twentieth century saw the introduction of two other means of distributing Communion, one was the reintroduction of an ancient practice, while the other was a uniquely new – and, in many ways, typically American – idea (Sack 2000). The ancient practice was intinction, dipping the consecrated Communion bread into the consecrated wine and eating both together. The 1990s saw the appearance of a fascinating variant to the individual common cup – prepackaged Communion. An Oregon pastor planned and produced a small plastic cup that included juice and a wafer of unleavened bread in separate parts. His church stated that this decreased Communion preparation time from 10 h to 40 min. Sold by a Southern Baptist publishing house under the name Remembrance, the product was available through Christian bookstores and used by thousands of mainly evangelical congregations as well as by thousands attending large Christian worship services, e.g., for practical purposes during worship at large stadiums (“Prepackaged Communion Takes Off” 1996). The prepackaged Communion sets were a creative redesign of an ancient rite to contemporary American culture with its preoccupation with hygiene, efficiency, and packaging. Both the ancient practice of intinction and the very contemporary invention of prepackaged Communion did not fully meet the desires of laypeople or theological scholars because the focus on drinking from the common cup and its meaning connected to unity with the Body of Christ was removed.

The Holy Communion, or Eucharist, stands at the center of Christian worship and is the model for all Christian meals. But eating in the church extends beyond this sacred meal, and we turn now to the social hall meals that also carry meaning for the church’s members and guests.

Food for Community and Social Action

Americans go to church for more than teaching, prayer, and worship; they also go for mutually satisfying social interaction and to receive care,

thus building a healthy community. Society in the 1800s challenged connections between people as early America was being established out on the frontier. People lived miles away from their nearest neighbors. As cities grew, everyone was a stranger to one another. A market economy stimulates competition over community, and when isolation is experienced, Americans hunger for community, for connections with other people (Sack 2000). Despite important developments in technology and the advent of social media in the late 1990s and its rapid advances in the 2000s, many people continue to feel isolated, or paradoxically so, because of technological and social media advances (Block 2006). Finding genuine community in church, specifically through its social events, fulfills peoples’ needs for belonging (Wuthnow 1994). Also, in a time when the church is one option among many for people to spend their time, this influences the church to include food in many of its functions as a means of attraction as well as meal fellowship fostering such community within its walls (Sack 2000). Though these food-centered social events are not in themselves inherently religious, church dinners and coffee hours nevertheless do play an important role for participants in the church. For these people, participating in a community is often the most important motivation next to attending worship in the church, and shared meals are often more important for creating community. These fellowship meals are a place where religious identity is shaped, community is built, and memories are created. They may not be religious, but they are not just another meal.

The first church meals in America were essentially served in very practical ways. Camp meetings at the beginning of the nineteenth century were temporary communities on the American frontier. Here, people gathered to worship, pray, and eat together (ibid.). For instance, in August of 1801, a revival held at Cane Ridge, Kentucky, tested the limits of such hospitality with over 800 people in attendance. The Cane Ridge Meeting House was one of the oldest church buildings in Kentucky. There were too many people in too small a space and few church kitchens and eating places nearby. Those leading this revival

remembered that they shared their food with guests, but soon the crowd grew so big that supplies ran out as there were as many as 140 wagons surrounding the church with people sleeping in their wagons or on the ground. They cooked for themselves and tied their horses in nearby pastures to graze. Even though the revival services were almost ongoing through the day, someone had to leave worship to tend the cook fires (Conkin 1990).

Other than camp meetings in the 1800s, however, there is little record of churches hosting meals simply for the sake of fellowship. Such social events awaited the time of the social congregation, which was a congregation committed to devotional practices during the late 1800s. In the early 1900s, to retain members and attract young people, Protestant churches planned activities differing from their current ministries, which included picnics in parks.

One approach to develop new ways of organizing social events by some denominations was the national church issuing “fun books” or “party books” through their publishing houses (Maguire 1953). These publications, especially made by Cokesbury Methodist Press for ecumenical audiences, provided ideas and suggestions for church social events. The goal of these social events was to lighten the burdens of life with leisure, yet also address serious problems of life (Depew 1932). All publications recommended activities and programs that provided refreshments or meals at church social gatherings and most provided menu ideas. With these elements, the fun books provided more than ideas for a successful program – they provided a middle-class Christian worldview (Sack 2000). The church of the late twentieth century and early twenty-first century has reflections of those early activities that were considered in resources like these fun books.

Church social ministry events and their meals are of a wide variety in the American church today; notable examples are as follows: a church hunter’s dinner following a meeting for deer hunters before hunting season begins, a Roman Catholic church holding a Friday night fish fry to support its parochial school, the men’s dart throwing league having conversation over sandwiches

following their competitions, benefit meals to raise funds for an ill church member or a member in the local community, a Jewish seder meal put on by confirmation students as an educational event, a soup kitchen on Saturdays that creates community between church members and strangers, the youth group gathering meal to inform the congregation about and raise funds for a mission trip they will take outside the country, or an Easter sunrise ecumenical breakfast provided annually by multiple church women’s groups. These are all functions of how meals support community togetherness or healthy community.

Religious or faith expressions during these events are also wide and varied. There may be a prayer before the meal, some readings from Scripture, and comments from a church leader regarding a ministry or mission, or the event does not have any explicit Christian or ecclesiastical elements and serves more as a party for those who attend.

Like centuries past and during different cultural times, the twentieth century and early twenty-first century has seen the church’s food events build community and present its members with models for togetherness. Adult dinners reflect gender roles, youth events encourage religious behavior, and family events build upon the value of community. As a congregation changes over time, so does the nature of its beloved meal fellowship occasions. For example, in the last three decades, there has been an increased trend of wedding receptions being held off church property for various reasons, e.g., the attraction of more amenities offered by a community dance hall for the wedding dance or the desire to provide alcohol or games that may be disallowed by the church.

Conclusion

New fellowship events in the church take the place of old ones. Annual events that at one time served special purposes and had large turnouts have since worn out, giving way to new customs and celebrations. There is little limit to the variety and creativity of Christians for uniquely

administering a sacred ritual like Holy Communion or for offering fellowship that nurtures church members and supports social ministries outside the congregation.

Introduction

Feeding and eating disorders were already described in ancient Greek times. However, it was only since the nineteenth century that they were labeled as medical condition. Diagnoses like *anorexia hysterica* and *anorexia nervosa* were used, referring to a psychiatric background. Nowadays, the two most commonly diagnosed eating disorders are anorexia nervosa and bulimia nervosa. Anorexia nervosa is less often diagnosed than bulimia nervosa but more known because of its acute risk of physical complications including death.

Next to anorexia nervosa and bulimia nervosa, the DSM-5 (APA 2013) classifies pica (persistent eating of nonnutritive, nonfood substances such as soil), rumination disorder (regurgitation of food, with rechewing, re-swallowing, or spitting out of the regurgitated substance), avoidant/restrictive food intake disorder (an eating or feeding disturbance as manifested by significant weight loss, nutritional deficiency, and so on), binge eating disorder, other specified feeding or eating disorders (including purging disorder and night eating syndrome), and unspecified feeding or eating disorder.

There is some debate whether (Obesity (also: ► [Childhood Obesity and Responsibilities](#))) obesity (► [Obesity and Consumer Choice](#)) is an eating disorder in the psychiatric spectrum as well. It is not a disorder in the DSM-5 or ICD-10, but it is recognized as a condition with major psychological and even psychiatric aspects. Other conditions that are related to eating and food but do not meet criteria for eating disorders as listed in DSM-5 or ICD-10 are, for example, dependence of laxatives and emetophobia (phobia for vomiting).

Outline

This entry will focus on anorexia nervosa, since ethical issues are most dominant in this disorder. Anorexia nervosa patients typically refuse treatment (► [Ethics of Dietitians](#)). If physicians want to enforce treatment, they need to establish that the patient is incompetent. First, the characteristics of anorexia nervosa, including the way in which it influences the body image, and the state

of the art in treatment are addressed. Next, the standard approach to incompetence is discussed, which focuses on cognitive abilities. Then, a critique on that approach is examined, in which the role of emotions is emphasized. After that, recent empirical ethical research is discussed, highlighting the importance of values in incompetence of anorexia patients. Finally, several ways of dealing with values in the context of the doctor–patient relationship are presented.

Anorexia Nervosa and the Image of the Body

The main characteristics of anorexia nervosa are the refusal to maintain body weight, intense fear of gaining weight (even though being underweight), and amenorrhea. Binge eating is often considered as a subtype of anorexia nervosa. Bulimia nervosa is characterized by excessive eating in discrete periods of time combined with a sense of lack of control and recurrent inappropriate compensatory behavior to prevent weight gain.

Anorexia nervosa is associated with personality traits and disorders, and the *anorexic personality* is described in literature (Tan 2006). This suggests a firm role of identity in the experiences of patients and perspectives on anorexia nervosa.

Anorexia nervosa is characterized by a disturbance in body, shape, or weight experience. Patients judge themselves to be fat and heavy, whereas in reality they are slim and have underweight. There are several hypotheses and models on the nature of anorexia nervosa. Neurobiological researchers emphasize the importance of feeling skinny (Kaye et al. 2013). Other researchers emphasize the role of body image disturbance, including low body esteem, associated attachment insecurity, and alexithymia in the etiology of anorexia nervosa (Keating et al. 2013).

State of the Art in Treatment of Eating Disorders

Eating disorders, and especially anorexia nervosa, are known for their great impact in the lives of both

patient and family. Anorexia nervosa can be and often is life threatening. Constant starving can give major physical problems, such as hypothermia, dependent edema, hypotension, bradycardia, and lanugo next to various metabolic changes. Amenorrhea is also a frequent sign. Even when treated successfully, these complications can have lifelong consequences (Sadock and Sadock 2007).

Patients, often (► [Feeding Children](#)) girls and young women (► [Gender Norms and Food Behavior](#)), usually come to medical attention when the weight loss becomes apparent. Then, the first consideration of most physicians and psychiatrists is to restore the patients' nutritional state. Psychological and psychiatric treatment, including individual psychotherapy, family education and therapy, and sometimes psychotropic medication come after that (Sadock and Sadock 2007).

However, most patients are not interested (► [Medicalization of Eating and Feeding](#)) in psychiatric treatment. A major textbook in the field of psychiatry suggests that compulsory treatment should be obtained only when the risk of death from the complications of malnutrition is likely. Guidelines and professional organizations also follow this line. When coercion is used, it is often to treat the physical complications. Patients are then rehydrated and forced to gain some weight. But this only fights the complications of anorexia nervosa and not the psychiatric origin of the condition.

Competence: The Standard Approach

Coercion is not often used in the treatment of anorexia nervosa and seldom for the psychiatric part of the treatment. Most women with anorexia nervosa are considered to be competent to refuse psychiatric treatment. Formally, competence means that a patient meets the legal requirements for providing informed consent. Most definitions of competence refer to decisional capacity or decision-making capacity, which is often understood as a cognitive or neuropsychological function (Eating and Thinking). The MacCAT (Grisso

and Appelbaum 1998), a major competence assessment tool, also has a cognitive focus. The MacCAT was developed in the last century by Appelbaum and Grisso based on four criteria: understanding, appreciation, reasoning, and expressing a choice (Grisso and Appelbaum 1998). Most international authors and researchers in the field of competence mention these criteria, some in slightly different terms or with proposals for amendments. The MacCAT is a translation of the four criteria in specific questions for patients (Grisso and Appelbaum 1998). The feasibility, reliability, and validity were described in their 1997 paper (Appelbaum et al. 1997). The conclusion is that in cases where competence is doubted, the MacCAT can help. A cutoff score is not defined. The MacCAT should always be combined with clinical judgment.

Research shows that MacCAT outcomes do not always overlap with clinical judgment alone. Patients with dementia are more often assessed as incompetent with the MacCAT than with clinical judgment alone (Vollmann et al. 2003). For patients with anorexia nervosa, it is the other way around: the MacCAT gives higher scores on their competence than clinicians do (Tan et al. 2003).

Experiences of Patients with Coercion

Tan et al. explored patients' experiences with coercion (Tan et al. 2010). They interviewed young women with anorexia nervosa about their opinions regarding forced treatment. Other research had already shown that women, when treated, can agree that coercion was needed. Tan et al. add three important new insights. First, none of the interviewees disapproved of the use of coercion in life-threatening situations, for both themselves and others. Second, the use of formal coercive measures was not regarded as essentially different from informal urging or pressure. In contrast, the way in which treatment (either coercion or pressure) was provided appeared crucial. In case of a good relationship with the health-care professionals and parents and an experience of support and respect, coercion was not labeled as

negative but as good care. Third, the women did not think that competence was an important subject. Again, not incompetence was a central criterion for them but their relationship with professionals and parents.

Most research and media attention on the subject of coercive measures in psychiatry is critical. Although coercion is not always perceived by patients as negative, and sometimes regarded as necessary, the way in which coercion is applied is often seen as problematic. Coercion is at odds with an attitude of consideration and mutual trust. These values, which are important in psychiatric care, are emphasized in virtue ethics. From this perspective, virtues like compassion and empathy are essential in good care. They also fit in the tradition of care ethics, in which good care is defined as engagement and involvement and in which relations are regarded as crucial, because people are dependent upon others to shape their lives.

Appreciation

The criteria of the MacCAT are not easy to define. The most difficult is appreciation. Appelbaum and Grisso (Appelbaum et al. 1997) distinguish between appreciation of disorder (the patient acknowledges that he or she manifests the disclosed disorder and all or most of the disclosed symptoms or does not agree but offers reasons that are not delusions and have some reasonable explanation) and appreciation of treatment (the patient acknowledges at least some potential for the treatment and some benefit, and the reason for refusal is not based on delusions or serious distortion of reality, or the patient does not believe that the treatment has the potential to produce some benefit, but offers reasons that are not delusional and have some reasonable explanation). Both elements have to be present. This notion of appreciation is still highly debated.

Some argue that appreciation should be replaced by acceptance of the need for care, because the latter term is more apt in capturing that aspect of insight by which a person with psychotic and manic disorders may be rendered

incapable of giving informed consent (van Staden 2003).

A systematic review of the literature on the subject (Ruissen et al. 2012) found a strong correlation between competence and insight, with overlap in psychotic disorders. Psychotic patients with poor insight are very likely to be incompetent, and psychotic patients with adequate insight are generally competent. In nonpsychotic disorders, however, another relationship emerges. Competence and insight do not completely overlap in these patients. Most incompetent patients in this group have poor insight, but nonpsychotic patients with adequate insight were incompetent in a substantial number of cases, including anorexia nervosa. In sum, anorexia nervosa patients with adequate insight can be incompetent.

An Alternative to the Standard Approach: Emotions

Critics of the approach of Appelbaum and Grisso question the central role of cognitive capacities. Charland underlines the role of emotions (Charland 1998, 2006). In important decisions in life, such as marriage, career, and parenthood, emotions play an important role. The same goes for decisions in health care. Emotions are related to personal identity and embody practical rationality; these issues should get more attention in competence assessment (Berghmans and Widdershoven 2003).

A Value Approach

As an alternative to a cognitive and an emotional approach, a third approach can be found in the literature: the values approach (Tan et al. 2003, 2006). The authors interviewed women with anorexia nervosa and their mothers about competence to make treatment decisions. The women proved to be able to discuss their reasons and choices for dieting. They knew the main aspects and details about treatment and acknowledged the consequences of their behavior, even recognizing

the possibility of severe physical complications and death.

The authors furthermore showed that for patients the value of “being thin” was most important in their lives, more important than friends, school, hobbies, and family. Some patients felt that anorexia was part of their identity. This suggests a fundamental shift in values due to the disease. The authors introduced the notion of “pathological values”: non-authentic values, changed or induced by a psychiatric disorder with an addictive character (Tan et al. 2003, 2006, 2010).

The authors conclude that these patients are not compromised in their cognitive abilities, but they do have a distorted value pattern. When using standard cognitive criteria, the women can be considered competent to refuse treatment. They acknowledge their symptoms, disorder, and the benefits of treatment. Yet, they refuse treatment anyway. The authors conclude that cognitive criteria are not enough for this group of psychiatric patients, as the competence of these patients is not compromised because of cognitive problems but because of a shift in values (Tan et al. 2006). Other authors follow this line (Charland 2006; Vollmann et al. 2003).

Dealing with Values in the Physician–Patient Relationship

When values are seen as an important aspect of competence and certain values are regarded as being influenced by the disease and therefore not authentic, the question can be raised whether these values should be simply discarded or can be addressed in another way. Should patient values in such cases be regarded as irrelevant, or might it be possible to deal with problematic values in a different way? Here, the work of Emanuel and Emanuel (1992) on models of the physician–patient relationship can be helpful. Next to following patient values in the standard informed consent approach (the informative model), or leaving them aside and act in the best interest of the

patient (the paternalist model), physicians can deal with patient values by helping patients to clarify their values (the interpretive model) or challenging them to reconsider their values (the deliberative model).

The interpretive model assumes that patients’ values are important, but not always clear. The physician should clarify ambivalences and support patients to find out which values are most important for them. When a refusal is based on short-term values (e.g., avoiding a feeling of control loss), while long-term values (e.g., health) are not met, a doctor can help to appreciate these values together with the patient. This model will, however, not be very useful in patients with eating disorders. Patients with eating disorders often do not need a doctor to clarify their values. The anorexia patient who refuses treatment and states that being thin is the most important value in her life has evidently made up her mind already.

In the deliberative model, the physician not only supports the patient in expressing and interpreting his or her values but also stimulates the patient to critically consider these values. The model implies that values are not static but dynamic and can change over time and influenced by changing circumstances. It does intend not only to make explicit the values at stake but also to develop them. This implies that the patient with anorexia nervosa is challenged to reconsider the value of being thin and to come and see that other values are also important in life. A physician who, in line with the deliberative model, challenges the patient’s values should be aware of his own values and take care not to impose them on the patient. He should also be aware that trying to change the patient’s views may involve moral dilemmas. Is pressure justified, or should the physician refrain from such means? Moral case deliberation can help professionals to reflect on dilemmas (Weidema et al. 2013). By investigating one’s own values, understanding the perspectives of others, and exchanging views in dialogue, participants in moral case deliberation can learn how to deal with moral dilemmas and further develop moral competence. Deliberation between professionals can thus create

conditions for applying the deliberative model of the physician–patient relationship in a responsible way.

Regardless which perspective on competence one endorses, it is important to try and strengthen the patient's competence as far as possible. When this is not possible, coercion can be necessary to reinforce autonomy in the long run (Tan et al. 2010), as a last resort. It may not always be possible to prevent switching to the paternalistic model. The moral justification of coercion, however, will be stronger if attempts have been made to address the patient in line with the deliberative model and foster reflection on values and moral learning.

Summary

This entry deals with ethical issues in dealing with eating disorders, especially anorexia nervosa as the most well-known example. If physicians want to enforce treatment, they need to establish that the patient is incompetent. First the characteristics of anorexia nervosa are presented, including changes in body experience and image, and its treatment. After that, the standard approach to incompetence is explained, which focuses on cognitive abilities; we specifically pay attention to the aspect of appreciation. Next, a critique on that approach is examined, in which the role of emotions is emphasized. Then, recent empirical ethical research is discussed, highlighting the importance of values in incompetence of anorexia patients. Finally, several ways of dealing with values in the context of the doctor–patient relationship are highlighted, including the contribution of moral case deliberation

Eating Disorders and Disturbed Eating

Shannon Burns Proctor
Department of Philosophy, Michigan State
University, East Lansing, MI, USA

Synonyms

Alimentary disturbances; Anorexia nervosa (AN); Binge-eating disorder (BED); Bulimia nervosa (BN); Compulsive eating; Eating disorders not otherwise specified (EDNOS); Purging

Introduction

Eating disorders are broadly defined as pathological or disturbed practices associated with food intake, weight management, and body image that can cause significant psychological and physical harm. The American Psychiatric Association identifies four central categories of eating disorders – anorexia nervosa (AN), bulimia nervosa (BN), binge-eating disorder (BED), and eating disorders not otherwise specified (EDNOS) – while acknowledging symptom overlap across these categories (APA 2000). It is estimated that several million individuals (approximately 90% female and 10% male when eating disorders are considered as a whole) are suffering from one of these disorders at any given time across the world (with the preponderance of cases occurring in the West). These disorders have proven particularly difficult to treat given the complex interrelations among individual, family, and social contributing factors.

The major ethical dilemmas concerning eating disorders arise out of disputes as to the ontological (i.e., how to understand) and practical (i.e., how to treat) character of these illnesses. Considerable disagreement exists among treatment providers, caretakers, and scholars as to the origins and nature of eating disorders, as well as to the best treatment practices. As for the ontological character, there is disagreement as to the identification of

these eating practices as pathological or disordered; whether the concept of addiction is useful or accurate in describing eating disorders; and to the degree of relatedness across the four categories as well as the emphasis placed upon AN at the expense of BN, BED, and EDNOS.

As for the practical character of eating disorders, there is disagreement about the importance of respecting a sufferer's stated desires (e.g., should a refusal of treatment be considered autonomous and/or competent), about the efficacy and value of force-feeding, and about whether and how treatment should incorporate analyses of various social oppressions. These ontological and practical matters are intertwined given that the understanding of eating disorders informs treatment practices and that treatment practices produce (or reproduce) particular understandings of these illnesses. The aim of distinguishing between the ontological-ethical link and the practical-ethical link, then, is to enhance clarity rather than to isolate these matters.

Understanding Eating Disorders

One of the central ethical issues concerning eating disorders is how to understand these illnesses, which have been variously identified as communicative practices, pathological or addictive behaviors, and indicators of broad social problems (Malson and Burns 2009). Judgments about the origins and meanings of eating disorders are ethical in nature because they shape treatment practices and attitudes toward sufferers and affect broader social views on food, weight, and bodies (Bordo 2004; Burns 2004).

Some have argued that eating disorders are communicative in nature – that the practices and harms associated with these illnesses are nonverbal messages in need of transcription (Bordo 2004; Burns 2004; Giordano 2007; Warin 2010). From this perspective, a main task of treatment providers is to understand the complex individual, familial, and social communications at work in eating disordered behavior. Often, though not necessarily, at odds with this view is the characterization of eating disorders as pathological.

The characterization of AN, BN, BED, and EDNOS as pathological behaviors, a characterization seemingly foundational to the very concept of eating disorders, has produced significant disagreement in the literature. The general argument in support of this characterization is that these practices are significantly distinct from average eating and food behaviors, that they produce psychological and physical harms that require medical attention, and that they can lead to death. The argument against this view emphasizes the negative outcomes associated with treatments based upon the pathological characterization. For example, researchers have demonstrated that the characterization of these practices as pathological produces a treatment context within which sufferers are disregarded, inhibiting the alleviation or transformation of their behaviors (Gremillion 2003; Warin 2010).

These disputes extend beyond semantic concerns; each side believes that the pathological characterization is a crucial factor in the establishment of treatment practices. Those in favor of the characterization tend toward the belief that treatment should renormalize patients' eating practices while those against tend toward the belief that treatment should open up new possibilities for life satisfaction.

There is also disagreement as to whether eating disorders are addictions. Some theorists have drawn comparisons between substance abuse and eating disorders, suggesting that 12-step programs can provide important support for those hoping to recover from their eating disorders. Others have challenged the accuracy and efficacy of identifying eating disorders as addictions, arguing that this label covers over important communicative aspects of disturbed eating practices, therefore inhibiting transformative treatment (Giordano 2003).

Another disagreement pertains to the separation of these disturbances into the four categories discussed above. Even as the American Psychiatric Association, Academy for Eating Disorders, and the National Institute of Mental Health acknowledge significant overlap and movement between the categories of AN, BN, BED, and EDNOS, it is commonplace for these disorders to be discussed in the literature as disparate, if

not discrete, illnesses (Stewart 2012). Beyond questions of the accuracy of isolating these inter-related eating practices are the ethical implications that arise when AN, BN, BED, and EDNOS are distinguished in this way. Scholars critical of these distinctions have argued that they produce a hierarchy wherein AN is taken to be the purist and most serious of the eating disorders by both eating disordered individuals and treatment providers (Burns 2004; Malson and Burns 2009).

The tendency to separate and rank eating disorders also arises in treatment responses, e.g., researchers have noted the frequency with which treatment providers prefer and cater to the needs of the non-purging anorexic while characterizing sufferers of BN, BED, and EDNOS as having less self-control and as being more troublesome in treatment (Burns 2004). In addition, theorists who focus upon anorexia have been challenged for confusing that which is particular to AN with eating disorders in general (e.g., for employing the language of "anorexia" and "eating disorders" interchangeably even when their remarks pertain exclusively to AN) and for misrepresenting the fact that AN is the least common of all the eating disorders (Malson and Burns 2009). Given this, contemporary theorists have argued in favor of deconstructing the conceptualization of, particularly, AN and BN as distinct disorders, preferring an account that attends to their interrelations (Burns 2004; Stewart 2012).

Force-Feeding and Anorexia Nervosa

Critics of the separation and ranking of eating disorders have noted that the emphasis on non-bingeing AN also manifests in the medical ethics literature on these illnesses. For example, the central ethical question taken up by theorists of medical ethics in regard to eating disorders is whether it is morally acceptable or justified to employ a nasogastric tube to feed an anorexic against her wishes (Draper 2000; Giordano 2003, 2007). However, while the question of whether to force-feed is most relevant for sufferers of AN, it is additionally relevant for cases of BED, BN, and EDNOS given the frequency with which questions about compulsory

treatment (other than force-feeding) arise with these patients (Draper 2000).

Compulsory treatment most typically aims at increasing a patient's weight, with measures including increased supervision (e.g., to prevent purging and exercising, to enforce bed rest, to ensure food consumption) or the introduction of a nasogastric feeding device (Tan et al. 2007). In the medical ethics literature, it is generally accepted that compulsory treatment can be justified only in the absence of a competent refusal. According to this standard, a patient's decision to refuse life-saving treatment is arguably competent even when it is at odds with a rational or reasonable decision (Draper 2000; Tan et al. 2007).

In terms of the eating disordered population, several factors complicate the determination of a patient's competency to refuse treatment (Draper 2000). For example, many eating disordered patients are minors whose parents are given the authority to make treatment decisions for them; eating disorders are considered mental illnesses, thus limiting patients' abilities to successfully argue their competency (at least in certain localities); doctors have been able to successfully argue that extremely low body weights significantly compromise patients' abilities to make competent decisions; and treatment providers have argued successfully in court that the *idée fixe* of eating disorders (i.e., the fear of fat) is at odds with any competent refusal of life-saving treatment (Draper 2000; Giordano 2003).

On the one hand, many proponents of force-feeding and other compulsory treatments argue that both autonomy and competency are utterly at odds with a diagnosis of anorexia. The basic position is that one has been taken over by her eating disorder and is, therefore, neither autonomous nor competent to make decisions regarding her food intake. Proponents of compulsory treatment argue that AN significantly inhibits an individual's ability to link up her refusal to eat and her fear of weight gain with the likelihood of her death, that it inhibits her capacity to be rational about her ability to recover, and that there are pathological values at work in AN that undermine her competency (Tan et al. 2007).

On the other hand, opponents of force-feeding highlight the lack of efficacy of such treatments (e.g., that long-term recovery rates for individuals who are force fed are worse than those who were not) and point out that there is a small, but significant number of cases in which an individual with AN is legally and ethically competent to determine that her quality of life is so poor as to be no longer worth living (Draper 2000). From this position, the force-feeding of an anorexic patient is at odds with generally accepted ethical principles such as autonomy and competency, meaning that even if a patient will die without a nasogastric tube, his or her wishes should be respected.

This argument against force-feeding has been met with a great deal of resistance, particularly because of the fact that AN is not considered to be a terminal or untreatable illness. Proponents of compulsory treatment have argued that it is unacceptable to allow a patient to die from an illness that, though difficult to treat, need not result in her death (Giordano 2003). Other researchers have criticized the very use of the frame of competency in eating disorder cases, noting that it fails to take into account the significant differences between these illnesses and the typical cases in which this frame is used. This position most frequently entails the argument that the particularities of eating disorders (e.g., the negative effects these illnesses have on thought processes) require treatment providers to consider the best interests of the patient and the welfare of the family when making treatment decisions (Giordano 2003).

Feminist Responses to Eating Disorders

Given that the preponderance of eating disorder patients are female as well as that gendered norms concerning food intake, weight, and appearance are central factors in eating disordered practices, feminist theorists have consistently argued that these illnesses are associated with Western femininity. Since the 1970s, feminist theorists have challenged mainstream responses to eating disorders – i.e., those employed in large-scale treatment centers, hospitals, psychiatric wards, and psychological practices. This scholarship

connects social and political analysis with ethical theory expanding the interpretive frame and practical considerations found in the medical ethics literature. Feminist theorists have variously addressed the social norms and institutions that contribute to the development of eating disorders, the manners in which treatment practices reproduce these same norms and institutions, the lack of consideration of what eating disordered patients have to say about their illnesses, the tendency of treatment providers to blame mothers for eating disorders, and the role of the media in the illnesses (Bordo 2004; Malson and Burns 2009).

More generally, it has been noted that this scholarship emphasizes the historical quality of eating disorders – that these are modern illnesses linked up with global development, an increasing technological presence (particularly in relation to media), and changing expectations concerning women's social roles and femininity (Bordo 2004; Giordano 2007). These considerations expand upon the medical ethics literature in that they incorporate social analyses into the understanding of eating disorders and demonstrate their relationship to gender oppression (LaVaquer-Manty 2001). From this perspective, eating disorders are understood to arise out of a complex interaction of individual psychological and physiological factors with oppressive social norms governing femininity, food, weight, and sexuality. Such considerations produce ethical accounts wherein a significant aim of treatment practices is to open up space to undermine and transform the effects of these negative social norms such that patients can be more free to construct a life beyond their eating disorder.

The cultural approach to eating disorders challenges the tendency of treatment providers to identify individual and family psychopathologies as the causal factors in these illnesses (Malson 1998; Bordo 2004). For example, Susan Bordo, one of the most well-known feminist scholars on eating disorders, argues that these illnesses represent what is wrong with society: they are, as she remarks, the crystallization of a pathological culture (Bordo 2004). In this view, eating disorders are the extreme result of problematic and contradictory norms surrounding gender that affect all

Western women's attitudes on food, eating, and body image. Her theoretical approach, which has been both widely adopted and criticized, seeks to disrupt the view that it is the eating disordered patient who is pathological, to demonstrate that cultural dynamics are the primary producers of these disorders, and to demonstrate that eating disorders are an extreme form of otherwise common Western female eating and food practices.

Similarly to Bordo's claim that eating disorders are on a continuum with other contemporary feminine eating practices, researchers have argued that these illnesses communicate something about Western culture and norms of femininity more generally (Malson 1998). According to this view, it is more valuable to analyze and deconstruct the social norms that constitute Western views on femininity and weight rather than to search for individual pathological explanations for eating disorders. For example, one of the central techniques employed by theorists of the cultural approach entails media analysis, which aims to uncover the pressure Western women feel to be thin, pure, and free of fat and to connect this pressure to the increasing rates of eating disorders.

Proponents of this view suggest that cultural analysis is necessary for an accurate understanding of these illnesses. For example, some scholars have argued that practices common in mainstream treatment facilities reproduce naturalized accounts of fitness, good mothering, and health, covering over the contentious histories of these ideals of well-being and, moreover, re-instilling these ideals into the patient, family, and staff as if they were eternal. The focus on individuals and families fails, according to this view, to interrogate cultural norms shaping women's attitudes and practices surrounding food, weight, bodies, and individuality itself. Alternatively, these theorists argue for treatment practices that uncover and challenge gender oppression, while opening up space for the individual to develop new relations to her body, food, and eating such that she can disrupt the effects of these norms.

Although feminists on average have regarded the cultural approach to eating disorders as an improvement over mainstream treatment responses to these illnesses, there are disagreements as to the

value of this approach for helping patients recover. For example, critics of the cultural approach note that while this view helps to identify the role of oppressive norms surrounding bodies, weight, and food intake (especially as they construct Western femininity), it fails to address the actual transformation of eating disordered practices. Among critics of the cultural approach, one set of theorists have argued that there needs to be greater consideration of the embodied or experiential nature of eating disorders in order to improve treatment outcomes (Malson and Burns 2009). These theorists claim that the proponents of the cultural approach fail to disrupt the individual/social divide they identify in mainstream analysis of eating disorders and merely shift from pathologizing individuals to pathologizing culture. They challenge that there are serious ethical implications for ignoring what sufferers have to say about their conditions (i.e., that eating disorders have something important to say about both the world and the individual). At issue here, then, is the degree to which sufferers' experiences provide necessary information as to how to best treat eating disorders.

Accordingly, critics of the cultural approach have argued that analyses of cultural contributing factors need to be paired with analysis of the bodily components of eating disorders. For example, Burns asks us to consider the value of understanding eating disorders as habitual practices – as bodily activities in the world shaped by (but not determined by) the cultural scripts that serve as the object of analysis for the cultural model (Malson and Burns 2009). Where the cultural approach focuses upon broad social norms and media images, researchers who take up a more embodied and experiential view on eating disorders consider the ways in which individuals create meaning through their eating practices.

In a related view, scholars working in fields such as anthropology, sociology, and philosophy have adopted a feminist phenomenological approach to understanding and treating eating disorders (Warin 2010). Phenomenological description and analysis is said to open up space for considering the highly particular communications that constitute eating disorders within a broader social analysis of the meanings of femininity,

weight, and food. The phenomenological approach entails detailed interviews of individuals with eating disorders and fieldwork at treatment centers with an aim of uncovering the hidden messages at work in both eating disordered practices and treatment modalities. These techniques create an opportunity for thinking about eating disordered behavior as a way of being in the world, where the individual's behavior is a unique yet meaningful response to her social possibilities.

Proponents of the phenomenological approach to eating disorders argue that they can help to establish or reestablish a patient's desire for the future by locating the transformative possibilities entailed in eating disordered behavior (i.e., by hearing what these practices have to say about the patient's world). The ethical quality of the phenomenological approach is found in its techniques that function to disrupt and transform disturbed eating practices without insisting upon a pathological reading of these same practices.

Despite the differences between the cultural and phenomenological approaches, both aim at expanding mainstream responses to eating disorders by incorporating an understanding of the interrelations between these illnesses and norms of Western femininity. However, it has been argued that theorists from both camps fail to interrogate these norms deeply enough (Malson and Burns 2009). As well, it has been argued that feminist theorists (as well as more mainstream treatment providers) unintentionally reproduce problematic norms about weight, bodies, and femininity in their work on eating disorders (Witt 1994). For example, scholars have argued that there are significant misconceptions about eating disorders in terms of who suffers from these illnesses as well as why individuals take up eating disordered practices (Witt 1994; Burns 2004; Saukko 2008; Warin 2010).

Misconceptions About Sufferers

Early scholarship on eating disorders tended to argue that sufferers were almost exclusively white women from well-to-do families who suffered from anorexia (Witt 1994; Gremillion 2003;

Bordo 2004; Burns 2004). As research progressed, it became clear that there was much more diversity in the population of eating disordered patients – e.g., sufferers come from a variety of racial, ethnic, and socioeconomic backgrounds, at least 10% of this population is male, and anorexia is actually the least common eating disorder. The ethical implications of these misconceptions are that they produce treatment practices that are ineffective in managing or transforming eating disordered practices for large numbers of patients (Burns 2004; Malson and Burns 2009).

For example, scholars have argued that racist and classist assumptions produced both misconceptions about who suffers from eating disorders and harmful treatment contexts for individuals who did not fit within these misconceptions (Witt 1994; Gremillion 2003). Particularly, it has been argued that women of color face significant hurdles in receiving effective treatment given faulty beliefs that communities of color are immune to societal pressures to be thin, lack of research into differences in access to and trust in mental health providers across communities, and prejudices among providers who perceive treatment resistance as fruitful in white patients and disruptive in patients of color (Witt 1994; Gremillion 2003; Bordo 2004). As well, Gremillion has shown that women of color in treatment facilities are frequently silenced, prevented from resisting treatment modalities, and threatened with a variety of punishments if they fail to comply with expectations (Gremillion 2003).

Another misconception about sufferers that has received attention in the ethical literature pertains to the role of thinness in eating disorders. While the majority of research on these illnesses emphasizes the fear of fat (e.g., getting fat, eating fat, feeling fat) and the desire to be thinner, certain scholars have begun to challenge the accuracy and effectiveness of identifying thinness as the core aim or meaning of disturbed eating practices (Burns 2004; Saukko 2008; Warin 2010). The argument is that a focus on the fear of fat and the desire to be thin inhibits a broader (and arguably more accurate) understanding of the eating disorders. For example, empirical data demonstrates that most bulimics are of average weight, the umbrella term of eating disorders includes binge

eatings who do not purge, and a sizable portion of individuals with eating disorders shift back and forth among the four categories of AN, BN, BED, and EDNOS (Burns 2004; Malson and Burns 2009; Stewart 2012).

Critics of this view argue that it fails to interrogate the fear of fat in order to uncover its meanings and motivations so that the reasons that sufferers focus upon thinness (when they do) go unremarked (Burns 2004; Warin 2010). Additionally, these critics claim that the focus on thinness in the literature tends to characterize eating disordered patients as extremely pathological in relation to “normal” women (given that most Western women are exposed to the same pressures to be thin). For example, Saukko argues that the claim that anorexia is about thinness casts the anorexic as a cultural dupe who is not strong enough to resist social pressure to be thin (Saukko 2008).

Others have challenged that the obsession with the “spectacle of thinness” (e.g., the use of imagery of highly emaciated women to engage and horrify the audience) manifests and reproduces the fear of fat it is meant to describe (Warin 2010). The focus on thinness has also been challenged given cultural associations of well-off white women with anorexia and women of color and economically disadvantaged women with BN and BED (Burns 2004). As well, Burns notes that the moral repugnance at overweight and obese bodies and the moral concern for underweight and anorexic bodies at the center of the spectacle of thinness reproduce oppressive norms on weight and food intake (Burns 2004).

In response to the criticism that eating disorders research is troubled by these various misconceptions, treatment providers and scholars have expanded their research in order to adequately consider the ways in which one’s location in various social categories (including eating disorder categories) shapes the experience of these illnesses (Malson and Burns 2009).

Summary

In summary, there is significant disagreement among treatment providers, medical ethicists,

and feminist scholars about how to understand and treat eating disorders. These disagreements are unsurprising given the number of individuals suffering from eating disorders, the severity of associated psychological and physical health problems, and the difficulties encountered in their treatment. The long-term ethical implications of these disagreements are as yet unclear – it may well prove to be the case that a variety of distinct understandings and treatment practices are necessary for the effective treatment of eating disorders.

Introduction

Dining etiquette is an elastic term whose definition varies drastically across space and time. There has never been, nor could there be, a universal and precise code of manners, and eating behaviors have developed over time according to codes of conduct and idealized styles of comportment within and across cultures. The act of dining occupies a somewhat ambiguous position in the realm of human behavior: eating is a fundamentally corporal activity, and of the several fundamental bodily functions, it is the only one that is carried out primarily in the company of others, including strangers. Due to its status as both an unavoidably carnal and deeply social activity, dining has developed complex codes of etiquette that attempt to convert the nutritional act of eating into an expression of social status and cultural facility.

Table manners are key indicators of cultural identity. Travelers to foreign countries often find themselves adrift among new foods, new cutlery, and new ways of eating. Even the etiquette rituals associated with dining that occur away from the table differ from community to community. In Korea, for example, it is impolite not to refuse a dinner invitation at least several times before attending, while in America a refusal is taken at face value (Kim 1986). Due to perceived notions of tact, British diners refrain from commenting on their food, while for the same reason, Japanese banqueters make a point of vocalizing their praise of the food at the table to signify appreciation (Visser 1991). The perpetual specificity in eating behavior leads to strong divisions between cultural groups. “Social norms such as table manners are rules and standards imposed by members of a social group,” write anthropologists Joly et al. (2008). Manners constitute an unspoken social code at the table, and those whose comportments do not fit the circumstances will find themselves excluded from the in-group at the table.

Eating behavior is contingent upon any number of circumstantial factors: location, company, time of day, occasion, and type of foods eaten, to name a few. This entry will trace the evolution of table manners in the western world in

chronological order by focusing on several influential people and publications that helped shape current fashion. The ultimate goal of manners is to ritualize or otherwise mediate the process of consumption. An established eating ritual prevents the unexpected, identifies the diner, and provides a model of conventional behavior. During the course of history, humans have regarded etiquette variously as indicative of morals, social behavior, or class background. The ethics of etiquette center on matters of self-governance: Is it possible to bring the natural function of eating under control to make it acceptable to others? If there is no attempt to observe the ritual of manners, then is does that insult those who witness it or those who have chosen to abandon etiquette? Ethics are defined as a group of moral principles that govern the behavior of an individual or group. When dining etiquette is breached, those principles are challenged.

Antiquity

Table manners almost certainly have existed since the first humans gathered together to eat. After making a kill, hunters would have needed to decide how to divide the animal and perhaps even who would get to enjoy the honor of the best portions. The earliest written records describing banquet rituals date back to the third millennium in Sumer and the second millennium in Syria and Mesopotamia (Flandrin 1999). In the Old Kingdom of ancient Egypt, circa 2500 B.C.E., manuals detailed instructions how to sit, what utensils to use, and how to set the table. Many of these rituals were rooted in religion, and the combination of food and prayer engendered customs that mediated the gap between the physical and the spiritual, many of which persist today.

Diners can display a lack of manners and, therefore, culture; or diners can display too much culture, becoming mannered – embodying culture to such an extent that they become overcivilized. In the classical world, manners and politesse were etymologically connected. The term “polite” shares a root with the Greek *polis*, or city. In Latin,

the word *civis*, which underlies civil and citizen, is defined as a dweller in cities. With cities came civilization: the pressures of proximal living in an urban environment create the proliferation of food choices. No longer is the domestic table the only source of food. When meals are taken outside the private sphere, manners govern the change from a private feeding process to a socially acceptable act.

Medieval Through Early Modern

During the Middle Ages, dining implements evolved slowly. The most famous example of this can be found in the history of the fork, which existed as a bi-pronged instrument used to hold meat in place while it was cut. In the eleventh century, a Greek princess in Venice was lambasted by Italian clerics for her use of the fork, which they claimed was entirely too fussy and sensual, proving inappropriate for a woman of her status. Most Europeans held food in place with their hands while cutting and brought food to their mouths by spearing it on the tip of the knife. Soup spoons were flat and circular until the fourteenth century when they grew concave and oval, while plates were more often trenchers (from the French *trancher*, to slice), pieces of flat bread or wood that protected the table from sauces and knife marks (Elias 1978).

A German lyric poet named Tannhäuser wrote the *Hofzucht*, a book of etiquette rules, in the mid-thirteenth century. Included in this treatise are many explicit instructions regarding the dinner table, many of which may seem unnecessary to modern diners. The *Hofzucht* specifies that gnawed bones should not be returned to the communal dish, that one should wash one's hands before eating, and that one should always eat with the outside hand to avoid elbow jostling. Even the highest nobles ate with their hands through the sixteenth century, meaning that the prescribed conduct for finger etiquette was equally as strict as it would be later for the fork. During the 1200s, the Italian Bonvicino da Riva wrote *Fifty Courtesies of the Table*, which instructed readers not to finger the rim of the communal glass, nor to

spit on the table – only expectoration under the table or against a wall was acceptable.

The Renaissance is notable for both its surge of writers interested in civility and its relative openness about bodily functions. In 1530, the Dutch humanist Erasmus published *De Civilitate Morum Puerilium*, commonly translated as “On Civility in Boys.” Considered to be one of the most influential Western treatises on manners for children, Erasmus’ work instructs the sons of noblemen on how to live a moral life (Leece 2011). Notable here is the link Erasmus traces between manners and morality: issues of ethical conduct extend to issues of social conduct in his treatise. Erasmus advises not to dip fingers in the broth and not to offer half-eaten food to a neighbor, and he warns that if there is a piece of food that cannot be swallowed, one should turn around discreetly and throw it somewhere. To act badly at the table reveals a lack of discipline and respect. However, Erasmus’s code of conduct is not so strict that he privileges conduct over health. He writes, “Fools who value civility more than health repress natural sounds” (Erasmus 1961). *De Civilitate* was translated over 20 times and became popular not only with the noble class, but with a much larger audience: the upwardly mobile merchant class that was rapidly gaining power and wealth during the early Renaissance.

In 1558, Giovanni della Casa wrote *Galateo: Or, a Treatise on Politeness and Delicacy of Manners*. Giovanni writes that spitting and coughing in company, “as some hearty fellows are apt to do,” is extremely indecent (Casa 1774). The *Galateo* also instructs people not to gape while at the table, sniff the dishes, nor offer anybody food that has already been bitten into. Notable is the change in behavior: for thirteenth century da Riva, spitting on the table is to be avoided; for della Casa some three centuries later, spitting anywhere in public is entirely prohibited. In another three centuries during the high Victorian period, spitting at the table was so uncouth it was not even mentioned as a potential faux pas. Other manners exhibit the same progression: what is censored in one century is forbidden in the next, and unmentionable by the “civilizing process” of several hundred years.

Seventeenth to Eighteenth Century

Despite Erasmus' notion that a man's character is revealed by his habits, it took nearly 100 years for manners to become a central part of how men were judged. Not until the seventeenth century did manners become the focal point of identification, when an increasingly stratified society sought to bring all human behavior under social control (Elias 1978). However, while this code of social protocol expanded in significance, it lost the moral aspect that Erasmus had considered the root of all conduct. With the centralization of royal courts in France, England, and Spain came the intensification of haute cuisine and the obsession with how to eat: the fork, which Queen Elizabeth I and her court eschewed, had numerous incarnations in the Jacobean court.

And significantly, during the seventeenth century, Europe received an influx of new foods from the Americas, Africa, and the Far East. Partaking of tea, tobacco, and coffee became a social activity, and coffeehouses proliferated as public spaces for discussion and digestion. Pamphlets were published, such as *The Rules and Orders of the Coffee-House*, published in 1674, illustrating codes of conduct for proper behavior. The coffeehouse was a space where men of a certain social standing could congregate, and so rules developed, creating hierarchies in seating placement and serving order.

Nineteenth Century

During the nineteenth century, the code of manners in the West reached an apex of complexity. The circulation of newspapers in the eighteenth century led to a rise in published manuals of all sorts in the nineteenth century, and etiquette guides proved particularly popular. The cookbooks and dining guides of the previous centuries, from Gervase Markham's *The English Huswife* (1615) to Elizabeth Raffald's *The Experienced English Housekeeper* (1769), assumed that their audience was, indeed, experienced. Cooking directions instruct the housewife who is familiar with the farm: "When you have killed and drawn

your ducks," begins a late eighteenth-century recipe for roast duck (Raffald 1775). Behavior at the table was similarly assumed, and the occasional manners guide published in this period more often lists behaviors to avoid than rituals to follow. A new, well-educated middle class was forming, and the increasingly literate population could now learn how the elite behaved. There was no overruling opinion on conduct, however, and many dining practices remained regional.

During the nineteenth century, cookbooks became much more prescriptive. The average housewife was assumed not to know what to serve for dinner or even how to serve it. *Mrs. Beeton's Book of Household Management*, first published in 1861 by Mr. Beeton's publishing firm, consisted of over 1000 pages and proved to be very influential in Great Britain, selling over two million copies in its first 7 years. Written for middle-class housewives, *Mrs. Beeton's* presupposes the presence of multiple servants at dinner and outlines the rules for a very formal and ritualized dinner. The butler, for example, brings in the first dish to dinner, removes the covers of the dishes, and handles wine throughout the meal, while the footman's duty is to assist him. Five to six plates per diner are used during dinner, and silverware is to be switched out after each course. Each cover is to be set:

... a knife on the right side of each plate, a fork on the left, and a carving-knife and fork at the top and bottom of the table, outside the others, with the rests opposite to them, and a gravy-spoon beside the knife. The fish-slice should be at the top, where the lady of the house, with the assistance of the gentleman next to her, divides the fish, and the soup-ladle at the bottom: it is sometimes usual to add a dessert-knife and fork; at the same time, on the right side also of each plate, put a wine-glass for as many kinds of wine as it is intended to hand round, and a finger-glass or glass-cooler about four inches from the edge. (Beeton 1994)

While these handbooks portrayed a lifestyle of unattainable wealth for its middle-class audience, Victorian readers internalized the ideal of incredible self-control and restraint at the table. Victorians experienced what Natalie Kapetanios Meir calls "a heightened regulation of individual behavior," resulting in a suppression of all

unbecoming bodily whims (Meir 2005). Despite these rules and regulations, manners were meant to be an extension of natural behavior: facile in expression and effortless in execution. As the etiquette of the time dictated such artifice in disguise of artlessness, the consequences of failing to follow etiquette rituals had ethical implications. Manners were crucial to social interaction, and a false step or flagrant disregard of the social code meant that the erring party was challenging the moral principles that governed the social collective.

With the rise in the importance of dining etiquette came an incredible diversification of dining utensils. Each implement became customized for a particular food: there was the silver fish fork, the elongated lemon fork, the bacon fork, the toast fork, the sardine fork, the joint fork, the baked potato fork, and the spork-like ice cream fork (Harlowe-Powell Auction Gallery). Similarly, each dish received a custom-made receptacle: gone was the bread trencher that was tossed or eaten after each meal. Instead, Victorian households accumulated bread plates, salad plates, soup bowls, and variously shaped wine glasses in place of the communal tankard. Adding to the confusion was a new trend of dining known as *service à la russe*, where dishes were brought in a succession of courses to the sideboard, where they were portioned and served hot. This trend, adopted in Paris in the 1830s and spread elsewhere, replaced the old European model called *service à la française*, where multiple plates were brought out at once to crowd the table and provide an image of plenty. In addition to, or perhaps because of, an increasingly diversified table, the Victorians created a code of manners so elaborate that a person's class, age, and nationality could be determined by the way he took tea.

Twentieth Century

The Victorian style of dining fell out of fashion as the pace of modern life quickened and an elaborate table and service began to seem cluttered and affected. Manner books, however, continued to exert influence over the dining public. Emily

Post published her tome titled *Etiquette in Society, in Business, in Politics, and at Home* in 1922, which quickly became a best seller. The differences between Mrs. Beeton's and Emily Post's instructions reflect the changes in mannered society within the span of 60 years. The two books overlap in scope: while *Mrs. Beeton's Book of Household Management* provides nearly a thousand recipes, instructions for servants, and models of comportment, Emily Post's *Etiquette* focuses almost exclusively on behavior. The cook and head servants are expected to devise the menu so that the lady of the house need not bother with actual methods of cooking. While Post's intricate hierarchy of manners may strike modern readers as distinctly Victorian, Post directly addresses and updates the outmoded fashions Beeton champions.

By the early 1900s, the dinner table had lost its large and elaborate centerpieces. The prevailing style now involved a pristine white tablecloth, polished silver, simple fresh flowers, and candles for pleasant lighting. Yet, while Emily Post criticized the Victorian penchant for accumulation, her fork recommendations are even more precise than those from Mrs. Beeton:

Then on the left of each plate, handle towards the edge of the table, and prongs up, is put the salad fork, the meat fork is put next, and then the fish fork. The salad fork, which will usually be the third used, is thus laid nearest to the plate. If there is an entrée, the fork for this course is left to be brought in later. On the right side of the plate, and nearest to it, is put the steel meat knife, then the silver fish knife, the edge of each toward the plate. Then the soup spoon and the oyster fork or grape fruit spoon. Additional forks and knives are put on the table during dinner. (Post 1922)

Post describes a method of eating she calls zigzag dining, in which food is cut with the fork in the left hand and the knife in the right, but the fork is switched to the right hand to bring food to the mouth. This style of dining originated in Paris during the eighteenth century, but eventually went out of fashion in Europe (Elias 1978). Why Americans continue to zigzag even today is unclear: possibly because the fork itself had caught on late in America and diners were not comfortable using the left hand to bring food to the mouth. Or,

it is possible that the Parisian trend was greeted in eighteenth-century America with such enthusiasm that the zigzag way of eating became solidly entrenched in culture.

The nineteenth-century French practice of dining in quick courses *à la russe* gained popularity in Europe and America, but ensuring that the entire table was served simultaneously required many servants. Emily Post writes that during “Russian” service, plates are to be cleared when an individual is finished to minimize the number of dirty dishes on the table at any time. Service *à la russe* prevented dishes from cooling and congealing at the table, which was quite unavoidable during a banquet-style *service à la française*. In *Etiquette*, Post adds a recommendation that butlers place a folded napkin between the palm and the plate if a dish is too hot to handle because the convergence of an entrenched silverware habit and service *à la russe* allowed food to be kept at higher temperatures when served (Post 1922). Hot food gradually became desired and expected, as heat represented freshness and exhibited the kitchen’s skill in timing.

With a more efficient table service than the Victorians, formal dining in the twentieth century remained a highly ritualized performance, often lasting hours. *Etiquette* contains entries instructing how to sit gracefully, how to enter a drawing room, and how to divide one’s attentions at a dinner party. A hostess was expected to “turn the table” after the second course, meaning that she turn and begin a conversation with the man on her left. At that moment, all guests were expected to end their conversations and begin anew with the guest to the left. Such strict rules for entertainment seem essentially Victorian; clearly, ideals of social self-regulation carried through the turn of the century. Not surprisingly, Post likens hosting a dinner party to swimming three miles out to sea – not for the inexperienced hostess.

Contemporary Manners

Emily Post died in 1960, at a time when America was undergoing a cultural revolution. Championing equal rights among races, classes, and genders,

the Civil Rights movement attacked many pre-existing standards of etiquette as snobbish, exclusionist, and unnatural. In reaction to the proper behavior of the previous generation, Americans developed new ways of speaking, dressing, and behaving. The hippie movement rejected the accumulation of material possessions and focused on naturalistic eating. Women were moving into the professional workplace, and Emily Post’s labor-intensive dinner party became representative of the sexist, binding expectations of an unenlightened society. Packaged foods presented efficient alternatives to cooking from scratch, and efficiency in the kitchen became more important than perhaps even the final result.

During the second half of the twentieth century, the exploration of ethnic foods and foreign ways of eating came into vogue. Members of the upwardly mobile classes learned how to eat with chopsticks or even with their hands, as various cuisines from around the world were “discovered.” European mannerisms were rejected as old-fashioned, and fully American methods of consumption (e.g., burgers, fries, and pizza eaten out of hand) were embraced as patriotic and unencumbered of pretension.

In response to this challenge to “civilized manners,” many critics bemoaned the modern American’s lack of tact; a code of enforced casualness creates the opportunity for rude and crude behavior, and lax table manners invite relapses into “barbarianism.” Judith Martin, known as Miss Manners, began an advice column in 1978 that gives wry advice to inquiring readers. The premise of her column is anachronistic: etiquette counsel for a modern and unmannered audience, but Martin’s ironic voice and authoritative good taste made her column indispensable. Published in over 200 newspapers worldwide, her column uses a question and answer format where readers could write in and ask questions ranging from wedding and funeral behavior to how to raise children. Compared with her predecessors, Miss Manners is notable for her sarcastic writing style, which through its formality and third person narrative pokes fun at being proper while at the same time extolling good etiquette as necessary for civilized behavior. While manners are proper,

they are not viewed with the same moral weight as they were in the fifteenth and nineteenth centuries. Instead, manners in the twenty-first century indicate less the ethical standards of a person and more about his or her class and nationality. The way someone behaves at the table indicates upbringing, not the moral state of the soul.

The state of manners in the twenty-first century is far less complex than it was even 100 years ago; nevertheless, in this digital age of universal exposure, new codes of conduct are abundant. During Medieval and Renaissance court banquets, the diners sat only on one side of the table, both to watch the entertainment and to be watched as entertainment (Elias 1978). In restaurants and households in the twenty-first century, we labor to create the illusion of privacy, but social media have prevented most gatherings from being truly private. There are codes of conduct about the use of smart phones at the table, but as with any new element, these codes are variable and constantly in flux. Screens at the table and around the table have modified eating habits, and diners must now navigate between the virtual and the actual.

The proliferation and popularity of diverse ethnic cuisines has vastly improved the palate of the average American, and facility in several cultural modes of eating is now expected. Diners who claim to be cultured are expected to manipulate chopsticks with ease, to know how to roll a taco, and to apply *injera* to a dish with only the right hand. It is true that enforced casualness in dining can lead to rude behavior, but with each development in restaurant form and function, a new type of etiquette develops.

Some mannerisms, such as the American zig-zag switch of the fork, are declining in popularity. Other traditions, such as formal dinner invitations, are seeing revitalized practice in an online format. With the “foodie” movement in the early 2000s, dinner parties are once again becoming increasingly elaborate, sans their former elaborate behavioral customs. Modern Americans in particular are very attentive to food authenticity and temperature (water must be iced, dishes should be still sizzling), but formal gatherings lack the structured behavior that characterized Victorian and early twentieth-century parties.

Summary

This entry traces some of the ways in which dining etiquette has evolved in the west from antiquity to the modern era. As dining etiquette evolves, it is instructive to watch how certain behaviors are tolerated, restricted, banned, and finally considered unthinkable. In addition, within the past century many preexisting rituals such as the butler announcing guests or the hostess turning the table have entirely disappeared. It remains to be seen how manners will develop to appropriately encompass the ever-quicken pace of living and eating. Already, unspoken codes of conduct have sprung up around eating on the go: eating in some forms of public transportation (e.g., busses) is frowned upon in many cities and outlawed in others, while coffee is assumed to be “to go” unless specified otherwise. Some restaurants of high reputation have banned food photography claiming it ruins the dining atmosphere, while others rely on crowd-sourced reviews for publicity. While it is difficult to predict the future of manners, it is certain that several hundred years from now, table manners in the twenty-first century will be used as both a positive and negative example of the beauties and idiosyncrasies of our era.

Eating Invasive Species

Joseph A. Tuminello III

 University of North Texas, Denton, TX, USA

Synonyms

[Gastronomical management](#); [Invasive species management](#); [Invasivore movement](#); [Invasivorism](#)

Introduction

While species have historically been introduced to new areas of the world in order to be used as food sources, many species are now being viewed as food sources subsequent to having been seen as invasive to an ecosystem. One management strategy is to encourage people to eat them. There are, however, also a number of economic, health, and legal concerns associated with eating invasive species.

Overview of Invasive Species Management

There are a number of conceptual issues regarding the criteria for determining invasiveness and nativity, as well as for ascribing terms such as “invasive,” “exotic,” “native,” and “nonnative” to members of particular species. Although agreement over definitions for these terms is not settled, invasive species are generally taken to be nonnative species that have detrimental effects on ecosystems and/or economies (Marks and Natural Resources Conservation Service 2006). There is continued debate over whether native species can become invasive if they exhibit certain destructive tendencies, as well as questions regarding how long a species must be in a certain location before it should be considered native, and even the adequacy of labels such as “invasive” (Tuminello).

In 2000, it was estimated that the United States alone spends about \$137 billion in annual costs due to damages from and control of invasive species. Invasive species are estimated to cause about \$400 billion in annual damages worldwide (Pimentel et al. 2000; Kirby 2003). While the introduction of nonnative species (which can subsequently become invasive) can occur due to “natural” means, human activity (largely due to travel and mobility) is the major cause of such introductions (Cox 1999). A variety of control methods are used as forms of invasive species management with the major categories consisting of chemical application, mechanical (or physical) removal, and biological

control, which relies on the natural predators of invasives (Simberloff 2001).

Introduction of Nonnative Species as Food Sources

Human consumption of nonnative species has a very long history. Many of the historical introductions of both plant and animal species have been tied to their use as sources of food. In fact, 98% of the US food system is constituted by nonnative species, such as corn, wheat, rice, cattle, and poultry (Pimentel et al. 2000). The introduction of mammal species to provide food for humans in Europe has been important since at least the eighteenth century (arguably earlier) surpassed only by the introduction of mammals for game purposes beginning in the late nineteenth century (Kraus 2003). Many fish species have been moved from the East Coast of the United States to become well established as food sources on the West Coast. Asian snakeheads (*Channa marulius* and *C. argus*) have recently been introduced as a food source in South Florida without authorization (Fuller 2003).

However, while there have been isolated examples in the past of the encouragement of eating invasive species as a control method (e.g., the consumption of nutria (*Myocastor coypus*) in Louisiana), the idea of eating invasive species as a way to significantly affect their populations has just begun to gain prominence as a management strategy in the last few years (Nuñez et al. 2012).

Eating Invasive Species as a Management Strategy: The Invasivore Movement

The consumption of invasive species as a management strategy is correlated with the recent emergence of the “invasivore” movement. This practice has caught on and been championed by a wide demographic including consumers, professional chefs, invasion biologists, and environmental organizations.

The Role of the Culinary Arts in the Invasivore Movement

Chef Philippe Parola was one of the first professional cooks to promote the preparation of invasive species as part of the culinary arts, marketing and developing recipes for nutria and Asian carp (*Hypophthalmichthys molitrix* and *H. nobilis*), a group of fish species which are taking over waterways and affecting native populations in the United States (Parola 2011). Chef Bun Lai of the restaurant Miya’s Sushi in New Haven, Connecticut, has recently gained notoriety for his use of (as well as his personal escapades foraging for) invasive seafood species in close proximity to his restaurant. He wrote an article in a special food-related issue of the magazine *Scientific American* describing recipes which include European green crabs (*Carcinus maenas*), European flat oysters (*Ostrea edulis*), and lionfish (*Pterois volitans*), a popular invasivore staple (Lai 2013).

Websites and Organizations Promoting the Invasivore Movement

The Institute for Applied Ecology, a nonprofit organization promoting conservation and habitat restoration, launched the *Eradication by Mastication* outreach, which consists of an annual “Invasive Species Cook-off” fundraiser, workshops such as the “Diggin’ It: Coastal Invasive Clam Dig and Workshop,” the cookbook *The Joy of Cooking Invasives*, and links to news articles and other websites focusing on eating invasive species and the invasivore movement (Eradication by Mastication n.d.). Websites such as *Eat the Invaders* and *Invasivore.org* contain a variety of resources for those wishing to do their part for the environment by eating invasive species, including lists of invasive species, hints and tips on foraging for and preparation of particular species, historical and biological information on invasive species, lists of books on the subject, and species-specific recipes such as “Dandelion and Burdock Beer,” “Blackened Snakehead with Piña Colada Salsa and Strawberries,” “Frog Leg

Piccata,” and “Kudzu Blossom Sorbet” (Eat the Invaders n.d.; Invasivore.org n.d.).

Books Related to the Consumption of Invasive Species

A number of books feature information on eating invasive species. Euell Gibbons’ 1962 classic *Stalking the Wild Asparagus* includes information on foraging, hunting, and cooking wild foods, including many invasive species (Gibbons 1962). Some cookbooks which focus on specific invasive species have been released recently, such as Tricia Ferguson and Lad Akins’ *Lionfish Cookbook*, of which sale proceeds go towards supporting conservation and lionfish research efforts of the organization REEF (Ferguson and Akins 2010). Hunting guide and writer Jackson Landers’ 2012 book *Eating Aliens* details Landers’ adventures hunting and eating invasive animal species, with chapters focusing on individual species such as feral pigs, Asian carp, nutria, and snakeheads (Landers 2012).

Concerns Over Eating Invasive Species

Although eating invasive species as a management strategy can educate the public, assist in early detection and rapid response efforts, and boost local economies, there are potential dangers in creating markets for invasive species as food sources. If members of invasive species become valuable commodities, then they may end up being protected rather than eradicated (Nuñez et al. 2012). People may also respond negatively to the loss of jobs or income due to elimination of invasive species if they begin to value their current welfare more than they deplore a negative ecological effect of the invasive species (Nuñez et al. 2012). Similar circumstances have already occurred, for example, regarding the economic importance of invasive woody plant species in the US horticulture industry and the importance of brown trout (*Salmo trutta*) in the New Zealand fishing industry (USDA 2010; Veitch and Clout 2001).

Promoting the Spread of Invasive Species

Another problem with eating invasives is that the importance of invasive species as economic resources may lead to their spreading and introduction into other places. Spreading of invasive species may occur by people imitating successful business models outside of areas where a given species originally became invasive and may also occur when viable parts of invasive plants are harvested, through unintentional dispersal of seeds, bulbs, etc. (Nuñez et al. 2012).

Cultural Attachment to Invasive Species

Cultural attachment to invasive species is another potential way in which using them as food sources can become an obstacle to the management of their populations. If the consumption of an invasive species becomes an important part of a given culture’s identity, members of that culture will likely be more reluctant to want to eradicate it. For example, wild boars (*Sus scrofa*) in Hawaii and wild horses (*Equus caballus*) in America have become integral cultural icons. Once a species gains cultural value, it can be protected and treasured by the locals even if it is nonnative and invasive (Nuñez et al. 2012).

Potential for Negligible Effects on Invasive Species Populations

Eating invasive species as a management strategy works as a supplement to the physical or mechanical removal of invasive species and, like all other management strategies, it must be employed in the right way in order to be successful. The successful control of invasive species populations depends not only on success rate in terms of sheer numbers of population members which are culled but also on other factors such as “harvesting” at the proper life stage to cause population declines. The harvesting of invasive species for food does not necessarily guarantee success. For instance, it may not be practical for people harvesting

invasive species for restaurants and local consumers to go to remote areas or places with low population densities, even if harvesting in these areas is important for ecological purposes (Nuñez et al. 2012).

Lack of Consumer Interest in Eating Certain Foods

Even if eating invasive species appears to be a viable management strategy in ecological terms, another issue is that people may have an aversion to, or may simply lack interest in eating, particular species. For example, the common carp (*Cyprinus carpio*) was introduced to American rivers by the government as a “miracle food” for the country, but never achieved popularity (Landers 2012). Recent studies, however, show a considerable market potential for Asian carp meat in the United States, which indicates that the negative public view of carp is reversing (Varble and Secchi 2013).

In an interview on the Leonard Lopate Show on the radio station WNYC in New York, Chef Bun Lai remarks that sea squirts (members of the subphylum *Tunicata*), while “beloved in Korea,” would probably not become an “overnight hit” in the United States and that he himself had to try them a number of times before beginning to enjoy them (Lai et al. 2013).

Research has been conducted recently on food neophobia, or a person’s willingness (or lack thereof) to try new foods. At least one study has indicated that food neophobia is correlated with a person’s willingness to pay to try new foods (Sanjuan-Lopez et al. 2011). Given the exotic nature of many invasive species, many people may be unwilling to try and/or buy them as food sources.

Health Risks Associated with Certain Invasive Species

Some invasive species are associated with potential health risks, which may act as another obstacle for the invasivore movement. Giant African land

snails (*Achatina fulica*), an invasive species in South Florida, may carry meningitis and other diseases, parasites, and toxins, including commercial pesticides (Sargalski 2013). Burmese pythons (*Python bivittatus*), which are invasive in the Florida Everglades, have been found to contain very high levels of mercury (Kessler 2010). The USDA points out that wild pigs are susceptible to swine brucellosis, pseudorabies, classical swine fever, and African swine fever (USDA 2005). In March 2013, the FDA warned that lionfish may contain ciguatoxins, which can lead to ciguatera fish poisoning (CFP), for which there is no known cure (News Desk 2013).

Legal Restrictions Regarding the Marketing and Sale of Invasive Species for Human Consumption

There are also a number of legal restrictions regarding the consumption and sale of invasive species. Agencies such as the USDA sometimes prevent hunting on lands that are being used for research, even if the area is public. In addition, besides fish, wild game is required to be killed in FDA-approved slaughterhouses before they can become commercially available to the public. This has posed major problems, for instance, regarding the marketing and sale of nutria meat, severely disrupting Philippe Parola’s plans to market the food in America and worldwide (Landers 2012).

Summary

This entry provides an overview of the nature and effects of invasive species and the role of the invasivore movement in the encouragement of eating invasive species as a way of reducing and/or eliminating invasive species populations. A number of websites, organizations, and books exist which promote invasivorism. At the same time, there are a number of concerns which have been expressed regarding the eating of invasive species, and these range from concerns over the success of the management strategy, as well as economic, health, and legal issues.

Eating, Feeding, and Disability

Elaine Gerber

Department of Anthropology, Montclair State University, Montclair, NJ, USA

Synonyms

Functional limitation; Handicap; Impairment; Medical model; Social model

Introduction

This entry addresses “disability,” both as a medical condition and as a social construction. In addressing disability as a medical phenomenon, the following topics are covered: malnutrition; obesity; GMOs, environmental toxins, and impairment; disability as an input; and food security and an underreporting of disability. The second section focuses on disability as a social construction and addresses the following topics: food choice, independence, and autonomy (including feeding tubes, assisted eating, and food choice); power and abuse; and food acquisition and access (including mobility impairment, identity, and inclusion). As the topic of disability is relatively understudied within food scholarship, the summary emphasizes directions for future research.

Definitions

Traditional notions of disability frame it as a medical phenomenon located in an individual’s body, and measures often define it by assessing functional ability, including level of severity. A common definition considers disability as something that “limits one or more major life activities” (e.g., Wendell 1996), including “being regarded as having” an impairment (e.g., the Americans with Disabilities Act ADA 1990). Being able to acquire food, cook, and eat all constitute major life activities.

Disability Studies scholarship, however, recognizes that a person’s ability to function can vary, depending on the type of environment one is in.

For example, wheelchair users are far less disabled in environments that do not rely on stairs, but that are instead built with ramps and wide doorways. Similarly, an individual with a severe facial disfigurement is disabled when a restaurant’s maitre d’ tells her that there are no tables available, even though she does not have any impairments that would limit her ability to eat. Accordingly, disability is not a fixed state, located in individual bodies, but rather a social process, including the experience of discrimination (see Oliver 1990). Although there is some debate

over definitions, generally speaking, “impairment” is used to refer to a bodily condition or disease, whereas “disability” describes the experience of a body in a particular physical, social, or cultural environment. This is referred to as a “social model” of disability.

A “social model” of disability distinguishes itself from the traditional “medical model” perspective by emphasizing the cultural variance in people’s lived experience of their bodies: what is considered disability varies from culture to culture and therefore is a social construction. This distinction is important in order to understand completely ways in which disability intersects with food and eating.

Person-First Language

It is current convention in American texts to use “person-first” language in referring to disability (e.g., “people with disabilities,” as opposed to “disabled people”). While “people-first” language emerged as a way to assert one’s humanity, by emphasizing the person as opposed to the condition, some scholars have critiqued this convention (see Titchkosky 2007). According to a social model, people do not “have” disabilities; they have impairments. They are disabled by environments. In Europe and elsewhere, the people-first convention is reversed. It is felt that “people with disabilities” locates the problem of disability within the individual rather than the social milieu, and therefore, “disabled people” more accurately describes the phenomenon of disablement as a process. Consequently, this entry avoids person-first language.

Disability as a Medical Phenomenon

Malnutrition

Disability is traditionally understood as a medical condition or negative health outcome (see above). Thus, “disability” appears in food studies and agricultural ethics primarily as a measure of malnutrition or undernutrition. The World Health Organization (WHO) defines “nutrition disorders” as “caused by an insufficient intake of food or of certain nutrients, by an inability of the

body to absorb and use nutrients, or by overconsumption of certain foods” (www.who.int/topics/nutrition_disorders/en/).

Nutrition disorders are particularly serious in children, since they interfere with healthy growth and development and can predispose people to many secondary health problems, such as infections and chronic diseases, thus reducing life expectancy, quality of life, and levels of productivity (see also “► [Food and Life Chances](#)”). Malnutrition affects significant numbers of people worldwide, in both developing and developed countries (www.worldhunger.org). People facing food shortages have a greater risk of contracting disease that can lead to disability or death. Accordingly, “disability” is caused by malnutrition (from poverty, war, drought, etc.). (See also “► [Food and Health Policy](#)”; “► [War and Food](#).”)

Obesity

Concerns with growing rates of obesity worldwide, and the secondary health consequences that result, also address disability as a medical condition. According to the WHO definition above, obesity is an outcome from the “overconsumption of certain foods” and thus frames obesity as a form of disability.

For most of human history, obesity and excess weight were a problem only among wealthier classes and in wealthier nations; more recently, rates of obesity have been rising dramatically in low- and middle-income countries, particularly in urban settings. The WHO estimates that obesity has more than doubled worldwide since 1980 (www.who.int/mediacentre/factsheets/fs311/en/index.html). The growth in obesity rates has been associated with changes in dietary and physical activity patterns linked to globalization. Importantly, environmental and social changes associated with development and the lack of accompanying policies to counter these changes in and across various sectors (such as health, agriculture, transportation, urban planning, food processing, distribution, marketing, and education) have had a disproportionate impact on poor people worldwide, including many disabled people.

Disabled people, compared to their non-disabled counterparts, are more likely to be sedentary and overweight and to experience the negative health consequences associated with those conditions (Kirchner et al. 2008). Note the secondary, negative health outcomes are a function of being sedentary and overweight and not a function of one’s initial impairment. Almost all people, even those with severe motor impairments, are capable of some physical activity, albeit with adaptive equipment or utilizing alternative strategies. However, disabled people generally receive little training from rehabilitation systems about how to exercise or how to cook and eat healthy food. (See also “► [Cooking Tools and Techniques: Ethical Issues](#)”.) As a consequence, many disabled people eat a “diet of convenience,” including “fast food” and pre-prepared, heavily processed foods. In addition to the advantages these foods confer for low-income populations generally (i.e., cost), they have added benefits to disabled people (e.g., with a “drive thru,” people with motor impairments do not need to navigate inaccessible interiors; consistent menus are easy to remember for people with cognitive impairments; people with visual impairments do not have to hope for a braille menu or rely on others to read the print version to them; etc.).

In conclusion, both these realms of “nutrition disorders” contain implicit ethical dimensions: because malnutrition and obesity are not equitably distributed in the population, they reflect larger concerns over issues of social justice and class inequality. (See also “► [Food and Class](#).”)

Genetic Modification, Environmental Toxins, and the Creation of Impairment

Although scientific studies are not conclusive, there is concern from an ethical standpoint about the use of genetically modified organisms (GMOs) in the food supply, particularly since labeling is not required in many countries, including the USA. (See also “► [GMO Food Labeling](#).”) Of major concern are the long-term health consequences that may result from the use of GMOs, as these have not been studied sufficiently prior to their release into food systems, and most

of the research conducted on their health effects has been conducted by the industry itself. There is similar concern over increased environmental toxins, in part because the use of GMOs often requires extensive use of pesticides, herbicides, and fungicides, all of which add to the cumulative levels of exposure that people encounter. (See also “► [Herbicide-Resistant Crops](#)”; “► [Food Risks](#).”) These products leach into groundwater and soil, thereby affecting a wider population, including people who never eat GMO products and farmers who inhale the pesticides directly. In other words, food systems may be creating illness and/or impairment, and doing so in ways that do not allow consumers to “opt out.” Pesticide exposure has been shown to generate impairment, from neurological problems to missing limbs to gastrointestinal and immune system disorders. It is unclear yet whether the use of GMOs (and/or the use of GMOs in conjunction with secondary products like increased herbicides) will also create additional impairment.

Disability as a Cause, Not an Outcome

In both cases of “nutritional disorders” mentioned above, malnutrition and obesity, the result is a negative health outcome, or “disability.”

However, it is also true that people are poor and malnourished, because they are disabled. Processes of disablement – the treatment of people who are or presumed to be impaired – including stigma, discrimination, and low expectations can cause economic inequality, poverty, and poor nutrition, among other outcomes. Although it is presumed that material hardship and low income result from disabled people’s functional limitations that prevent their full participation in productive economic activity (see Hiranandani 2009), the truth is that the link between poverty and disability is more complex and multi-directional. (See also “► [Food and Class](#).”)

Revisiting the functional definition above, the assumption is that disabled people are inherently unable to work, that being unable to work is what defines someone as disabled. For example, in order to qualify for “disability benefits” in the USA, an individual has to be certified as unable to work. Yet, in reality, many disabled people can

and do work. And many more could, if barriers to employment – such as discriminatory hiring practices, attitudinal barriers, caps on earnings in order to maintain benefits (including much needed health insurance), limited and poor quality education, training, and “rehabilitation” services – were removed. This is an ethical issue as disabled people around the globe are more likely to be poor than are their nondisabled counterparts. They are also more likely to be unemployed and, when they are employed, to earn less than nondisabled people.

In addition, there are many other types of impairments besides “nutritional disorders” that can cause food insecurity and limit access to and acquisition of sufficient, desired foods. For example, having motor impairments may limit people from accessing emergency food aid or make getting to the grocery cumbersome, if not impossible, in certain environments. (See also “► [Food Assistance and International Trade](#)”; “► [Grocery Store Design](#).”) These are discussed in greater detail below.

Food Security and an Underreporting of Disability

(See also “► [Food Security](#).”)

The presence and impact of disability – even from a “medical model” – is insufficiently examined within studies of food security, despite the evidence that people with a wide range of impairments have added difficulty obtaining sufficient food on a daily basis and in emergency contexts. A collection of essays in *Human Organization*, for example, highlighted the difficulty disabled people have in both natural and man-made disasters, as conventional disaster planning and response – including access to food aid – tended to perpetuate existing social inequalities (Fjord et al. 2009; Merten and Haller 2009; Gwatirisa and Manderson 2009). (See also “► [Food Assistance and International Trade](#).”) Similarly, recent work by Groce (2012) indicates that there is not usually an equitable “trickle-down” effect of food distribution to disabled people within communities, nor within the household. From an ethical standpoint, this raises serious concern: disabled people are one of the most marginalized

populations facing food insecurity, and yet awareness of this is hardly recognized by scholars and activists seeking to redress hunger and unequal access to food.

There are multiple reasons for this. For one, “disability” is not on the intellectual radar of many food scholars; it has yet to be fully recognized as a demographic characteristic on par with race, class, and gender. For another, prevalence estimates of the presence of “disability” (or more accurately, impairment) are underreported. Questions about it do not appear on many standard instruments used by food scholars, nor within more open-ended, flexible surveys and during interviews. While scholars do not necessarily look for “disability,” people also do not always report it in ways that researchers expect. For example, people may not have a disabled identity or consider themselves disabled, even if they experience so-called functional limitations. Disability is a heavily stigmatized status that people may not want to personally acknowledge or claim that they have. Furthermore, what is considered “disability” varies from culture to culture (see Ingstad and Whyte 1995), including between the culture of the researcher and local participants.

Nonetheless, ethnographic data has begun to document the presence of impairment and ways in which it limits food acquisition and eating. For example, people report “having bad knees,” “occasional headaches,” a “bad back,” or “fatigue” that limits their ability to shop and/or carry home groceries, particularly if they rely on public transit (Webber et al. 2007; Gerber 2012). In a study among low-income households, Webber et al. (2007) found the prevalence of disability surprisingly high and that the trade-offs people made (e.g., convenience of a local grocery, good wheelchair access, best prices) intersected with impairment far more than previously supposed. Their research indicated that even people without a disabled identity, people who do not think of themselves as disabled and who therefore might not respond affirmatively on a standard instrument of food security, frequently had their bodies impact their ability to shop, make purchasing decisions, and carry home groceries. This was true, even when the primary shopper in the

household was not impaired: having a disabled family member impacted household food security, as it created constraints on both time and budget. Disabled people are also often limited in their choice of foods. For example, many older adults, people with visual impairments, people with cognitive impairments or brain injury, among others, may have difficulty reading or understanding package labels. (See also “► [Food Labeling](#).”) And any individual, regardless of impairment type, that is reliant on others to shop for them, even when providing a clear list and instructions, is essentially subjected to the whimsy and interpretation of others. If disability is seen as an *input* (rather than an outcome) that limits food acquisition, studies might examine it more. Similarly, understanding “disability” as more than a medical condition – as a social construction, rather than a medical or biological fact – might also increase the presence of it in food studies.

In conclusion, issues of food security are also disability issues, and scholarship should reflect that fact. (See also “► [Food Security](#).”) Because of the association of disability and poverty and the association of hunger, obesity, and food insecurity to poverty, any project that examines food deserts or the obesity epidemic is, by definition, examining a disability issue. Moreover, these issues disproportionately impact disabled people. Compared to the nondisabled population, disabled people are more likely to be overweight, sedentary, and experience the health consequences that result. In other words, food security is a disability issue: the effect of globalization on food access is felt particularly hard by disenfranchised populations, which – by definition – include many disabled people.

Disability as a Social Construction

Food Choice, Independence, and Autonomy

(See also “► [Taste, Distaste, and Food](#).”)

Access to food, control over food choice, and eating for disabled people are often balanced with a need for assistance. Nonetheless, or perhaps because of this, food and eating serve as important and symbolically laden sites through which

people contest their identity and/or mark their independence. In western cultures, being able to feed oneself symbolizes independence and acts as a marker of adulthood. Difficulty achieving social adulthood for disabled people accentuates the stigmatizing aspects of disability. Research reiterates the point that food practices not only reflect cultural assumptions but define and maintain them. (See also “► [Ethnicity, Ethnic Identity, and Food](#)”; “► [Race, Racial Identity, and Eating](#).”) Disability Studies scholarship has identified the continued infantilization of disabled people (Longmore 2003), and one way this is done is through control over food and eating.

Feeding Tubes/Gastrointestinal Tubes (G-Tubes)

(See also “► [Medicalization of Eating and Feeding](#).”)

The case of Terri Schiavo, a Florida woman in a “persistent vegetative state,” received nationwide attention and prompted a nationwide ethics debate in the USA over the right to die. In “Death with Dignity” Acts and in other forms of assisted suicide, the assumption is that withholding food, or withdrawing feeding tubes, is an acceptable form of euthanasia, although this has been contested by many disability rights advocates, including the group Not Dead Yet (www.notdeadyet.org), which considers euthanasia as a deadly form of discrimination against elderly, ill, and disabled people.

G-tubes also highlight the very cultural nature of eating practices and why some are seen as acceptable and others not. Some cultures eat with their hands, others with knives and forks. The fact that in western cultures eating with a straw in the mouth is seen as “yum” while a straw in the belly is seen as “ick” is an example of cultural relativism.

Assisted Eating

Similarly, context matters in the case of assisted eating for people with motor impairments. (Note: people with motor impairments is a broad category, including people with full paralysis or quadriplegia, lack of limbs or digits, multiple sclerosis, etc.). Interdependency is culturally acceptable for

children, because children in western cultures are expected to be dependent and, therefore, need help eating. Adults routinely feed babies as an act of love. But cultural expectations for adults are different: being an “adult” in American culture, for example, means being independent, including providing for and feeding oneself. Using a personal care attendant (PCA) to help with meals is stigmatized, to the point that it might prevent people from participating in public and private events that involve food and from receiving the benefits of sociality that come from breaking bread together (see, e.g., Lance 2007). But this is not a “given” or necessary function of one’s impairment, as much as it is a reflection of one’s culture. For example, in Ethiopia, adults routinely feed one another as a display of friendship and as a common practice that reinforces the intimacy of social relations. Even in the USA, feeding one another can both generate and reflect intimacy, such as between romantic couples. However, for disabled people, needing help eating does not generate a positive form of interdependence, but rather invokes the cultural notion of “eating as independence” so pervasive in American culture and thereby reinforces their disabled status.

Food Choice

The idea that there are certain foods that are “kids’ foods” and other foods that are reserved for, or preferred by, adults is not found in every culture. However, in cultures where this distinction exists, this symbolism is another way that disabled people can claim an adult status or, conversely, be treated as children. As noted above, disabled people are considered dependent, a quality often associated with children, and often treated as perpetual children, or childlike, even once they reach biological ages associated with adulthood. As an example, many adults – with various types of impairments, from blindness to post-polio syndrome – report being offered sweets, a gesture normally reserved for young children (Finger 2007, Gerber personal communication) and a gesture that reinforces the notion of disabled people as dependent(s). Similar examples exist of disabled people wanting or being offered all the

accoutrements of a child's birthday party, including party hats and frosted cupcakes, even when all other adults present are served different types of desserts (Davies 2007). (See also "► [Taste, Dis-taste, and Food.](#)") Likewise, controlling access to candy and other snacks particularly during adolescence and for "transition-aged" youth can become an area of conflict between young disabled people and their parents or caregivers. Having culturally and age-appropriate foods matters because they shape boundaries of inclusion and exclusion. Given the importance of sociality that occurs around eating, issues of food choice are not inconsequential. Likewise, being able to choose what one wants to eat, when, and with whom is an important aspect of independence and one's self-identity.

The issue of food "choice" intersects with impairment in other ways. For example, some food "choices" are not really choices at all, but a necessary accommodation to a particular and/or non-visible impairment. People with diabetes, depression, irritable bowel disorder, chronic fatigue syndrome, multiple chemical sensitivities, celiac disease, and food allergies, among other conditions (see also "► [Food Allergies: Ethical Issues](#)"). may have dietary restrictions that appear as "choices," but which dramatically impact one's health and well-being. To frame food decisions as "lifestyle choices" belittles the reality that many disabled people face. It also raises questions about how dietary preferences are accommodated or, rather, which ones are and which ones are not, in both public venues and private dining settings. Ethically, it further raises issues about inclusion of disabled people in the sociality of eating. That is, eating practices and limited food choice can be forms of "culinary exclusion" that prevent disabled people from reaching adulthood status, participating in social events, or acquiring full cultural citizenship.

Power and Abuse

(See also "► [Punishment and Food.](#)")

Since access to food, control over food choice, and help eating is balanced with a need for assistance for many disabled people, it is often, unfortunately, also a site of abuse. Control over food is

a form of power that, in the extreme, serves as a way to oppress people and, in less extreme forms, perpetuates the infantilization of disabled people. Although prevalence data is rare, there is evidence suggesting that both forced feeding of and the withholding of food to disabled people occur with regularity. It has been most well documented among institutional care settings but is beginning to be recorded among group home and assisted living facilities as well (e.g., Moyer 2007; Taylor and Bogdan 1998). It certainly also occurs among personal relationships, with feeding by both paid and unpaid caregivers. Both first-person and ethnographic accounts have highlighted the range this abuse takes: from withholding "specialty items" brought by family members to using food as leverage to "correct" behavior issues, to locking refrigerators and kitchens "after hours," and to outright theft, starvation, and more. It is particularly disturbing from an ethical standpoint that so much of the systematic "food abuse" occurs to people who are the least powerful to do something about it, such as people with cognitive impairments living in institutional settings. The examples provided are reminders that it is not only people with motor impairments who need assistance eating and who are subject to food abuse. Nor is this issue exclusive to disabled people, as older adults in institutional care and living at home have reported being denied sufficient food.

Control over food is a form of power and an important and under-recognized site of disability abuse.

However, food has also served as a site of resistance, such as hunger strikes and food riots. (Note: hunger strikes can also create impairment.) (See also "► [Fasting](#)"; "► [Food Riots, Historical Perspectives.](#)")

Food Acquisition and Access

"Access" means different things to the disability community than it does to food scholars. Most obviously, it has come to be synonymous with physical accessibility for disabled people (e.g., Is there a ramp? Will items in the market be placed low enough on shelves to be reachable? Are the aisles wide enough to accommodate the use of a

powerchair and service dog?) (See also “► [Grocery Store Design](#).”) The goal is to provide universal access: building physical environments that permit the most access to the most people, following principles of universal design. This would apply to the acquisition of food in markets, the ability to dine in restaurants, and the “visitability” of private homes. “Accessible design” and “aging in place” guidelines have architectural specs that include lower kitchen counters to accommodate wheelchair height. A broader understanding of physical access might also include alterations to lighting for people who are lip reading or using sign language and to noise levels for people who rely primarily on auditory cues. Accessible design guidelines, however, have been less commonly applied to the domain of social participation. Buffets, for example, are notoriously difficult to navigate, especially for people who use support canes and crutches and for people who are visually impaired.

The section on food security above highlights some of the issues that disabled people face in acquiring food. Like many people with limited means, disabled people often rely on public transit to navigate their local food environment, although they do so with added complexity, such as using a long cane or guide dog in addition to their groceries. Moreover, much public transit is only somewhat “accessible.” Truly accessible transit remains a huge problem for mobility-impaired persons. Having fresh produce on market shelves is not considered “available” from the consumers’ point of view of their local food environment, if they cannot get to it.

Mobility Versus Motor Impairments

The WHO’s International Classification of Functioning, Disability, and Health, or ICF, (www.who.int/classifications/icf/en/) distinguishes between “impairments” (characteristics of body structure and/or functioning) and “activities” (social behaviors). Accordingly, “mobility” means relating to physical activity and social participation, whereas “motor impairment” refers to bodily movement. However, contemporary culture conflates “motor” with “mobility” to the extent that, in common parlance, these terms are

used somewhat interchangeably. Yet they mean very different things. For example, people with motor impairments may need assistance eating (see above). But many more people have mobility impairments and not just wheelchair users. For example, people with cognitive impairments, brain injury, or dementia may have difficulty following directions or forget how to get where they are going. People with communication, language, or speech impairments may have trouble asking for directions, if they become lost. People with psychiatric impairments may find leaving the house incredibly difficult, if not impossible. The field of blindness has an entire profession (i.e., Orientation and Mobility) to teach people with visual impairment how to get from Point A to Point B. In fact, all but the seasoned pedestrian may have mobility limitations when navigating dense streetscapes with heavy traffic and no sidewalks. In terms of food acquisition, it is important to distinguish between motor and mobility impairments, as both the problems and solutions may differ. Likewise, food scholarship needs to recognize that “access” has to include more than just physical access for wheelchair users. (See also “► [Food and Place](#).”)

Identity

“Access” also means many other kinds of access beyond the physical, built environment. It also means access to the full range of institutions, roles, and identities available in a given society, or what anthropologists consider cultural citizenship. And theories of identity are tied to theories of consumption, perhaps nowhere more clearly than regarding food and eating. (See also “► [You Are What You Eat](#).”) Food has become a new marker of class status (i.e., what one can afford to eat and where is understood as a reflection of one’s taste and character). (See also “► [Taste, Distaste, and Food](#)”; “► [Food and Class](#).”) Likewise, as food has become central to consumer-based experiences in popular culture, it also generates new, elite identities, where taste becomes laden with moral superiority (e.g., vegans, “foodies”). (See also “► [Virtue Theory, Food, and Agriculture](#).”) There is a form of moral value that comes with being able to claim these

identities that is out of reach to many disabled people. These elite identities are another form of culinary exclusion (i.e., who can afford to buy local, organic, and fair trade) that reinforces the social position of disabled people. (See also “► [Fair Trade in Food and Agricultural Products](#)”; “► [Public Institutional Foodservice](#).”)

Note: there are members of the disability community who are vegans for political (as opposed to health) reasons, as they make the connection between the treatment of animals and the treatment of disabled people (e.g., Taylor 2011). The parallel is not based on being treated poorly, as animals, nor from being “trapped” in a disabled body, like animals in a cage, but centers on a critique of an oppressive, capitalist values system that designates certain bodies as normal (and hence capable of labor), others as broken, and some as acceptable sources of food. (See also “► [Animal Welfare: A Critical Examination of the Concept](#)”; “► [Meat: Ethical Considerations](#).”)

Inclusion and Exclusion

A broader definition of access raises the questions about who does not have, metaphorically and literally, a seat at the table. For example, people might not be deaf enough to need a hearing aid or have learned to sign, but nor do they hear well enough to participate actively in a dinner table conversation. This would include many people who have difficulty hearing because of room acoustics or age-related hearing loss. Similarly, people who are not blind enough to carry a white cane or use a guide dog may still have difficulty recognizing colleagues at a restaurant or social event. Likewise, people who “express themselves in non-normative ways,” such as those with speech impairments, those on the autism spectrum who may not follow sarcasm, and those with psychiatric impairment (sometimes considered “eccentric,” “weird,” or “a little off”), are often not invited to the table. These are examples where discourse serves as an ideological barrier to inclusion and sociality.

Culturally acceptable boundaries around inclusion and exclusion regarding food increasingly define who and what is considered disabled.

Thinking through the notion of “access” complicates the understanding of “food-related”

impairments. Moreover, thinking about disability from a social model perspective shifts the focus of the “problem” from the person to the environment.

Summary

Societies around the globe structure inclusion/exclusion, citizenship, and personhood through rules about food and eating, and scholarship should examine ways in which local and global food systems and their politics and proscriptions highlight the very cultural nature of “disability.” There is theory both within and beyond Disability Studies that emphasizes interdependence over independence (see, e.g., Heldke 2009). Likewise, Hiranandani (2009) ties disabled people’s well-being to the larger food sovereignty movement, arguing that only by working together and improving circumstances for the most disenfranchised sectors (i.e., disabled people) can all people’s well-being be improved. Other research, such as that by UK’s Leonard Cheshire Disability and Inclusive Development Centre, is beginning to explore agriculture as a component of livelihoods for disabled people in urban slums and rural settings and the constraints and barriers they face (see <http://www.ucl.ac.uk/lc-ccr/ccdrp/projects/riu>). This is important research that will also measure the effect of home gardens on disabled people’s nutritional status and the availability of food in their households. Beyond these few works and the others discussed above, there is little scholarship on disability – especially the social model of disability – within food studies. Therefore, this summary focuses on directions for future research.

There needs to be work that defines the scope of the field. Statistical data about the global population of persons affected by both disability and food insecurity is needed as is work that highlights the affect of a global, transnational economy on food security and disability. More cross-cultural research would be incredibly helpful.

Given the cultural and biological importance of food – which includes nearly every social encounter from the business lunch to networking opportunities and to ritualized and religious

events – people are financially and socially disadvantaged by an inability to “break bread” together. Future research should measure the financial and social loss that results, as well as the impact of this discrimination in different settings, according to a variety of demographic variables across disability, such as gender, ethnicity, and obviously, class. It should also explore the political conditions that structure these situations.

Scholars might be interested in further considering the impact that a food-centric perspective can have on topics important to Disability Studies, such as:

- The politics of end-of-life care, G-tubes, and food refusal
- The construction of unpaid, nurturing work surrounding assisted eating and food preparation as “care”
- How impairments alter social and cultural aspects of “etiquette” about eating
- Implications of disability-related dietary restrictions on social acceptance
- Expanding food choice for people living in group homes and institutions
- Ways visitability, access, and independent living are altered by a concentration on food

At the same time, food studies scholarship can also benefit by expanding research to include a disability perspective on a number of mainstream issues. For example:

- How global, capitalist approaches to food production, distribution, packaging, and cooking shape “bodies” around the world, including the construction of disabled bodies. How are ideas of “naturalness” transferred from ideas about food to ideas about bodies (or vice versa) and what are the implications for disability?
- How social mores and stigmas around eating etiquette affect who is considered disabled around the globe. How are relationships, expectations, and choices around food contested and negotiated by disabled people?
- Ways in which the “gentrification of taste” affects certain segments of the population,

such as people with severe allergies; people who use gastrointestinal tubes to eat; people who receive “disability benefits” and therefore have limited income; and others.

- Cultural analyses that focus on the artifacts of “foodie culture” and its targeted audience, to examine among other things whether these products are limited to certain types of bodies, are accessible to all bodies, or create new forms of disablement.
- Are community-supported agricultures groups (CSAs) and other local forms of food sovereignty accessible to and inclusive of disabled people? How can food systems be made more accessible to people with all kinds of impairments? (See also “► [Community-Supported Agriculture](#).”)

Eating, Feeding, and the Human Life Cycle

Helen Vallianatos

Anthropology, University of Alberta, Edmonton, AB, Canada

Synonyms

Biocultural; Growth and development; Life stage

Introduction

Humans, like all biological species, have their own pattern of ontogeny, that is, the process of growth and development originating with conception and ending with death. This pattern involves biological, behavioral, mental, and emotional development and maturation and has been divided into stages: the three trimesters of prenatal life, the neonatal period, infancy, childhood, juvenile, adolescence, adulthood, elderhood, and senescence (Bogin 2001, Chap. 3). Each stage has its own particular nutritional requirements and culturally based understandings of appropriate eating practices. This entry reviews the ethical issues arising from eating and feeding practices in the aforementioned life stages, albeit combining the discussion for some of these stages.

Birth and Infancy

The neonatal period, the first 28 days of life after birth, is characterized by rapid growth and adjustment to life outside the womb, such as temperature fluctuations. The primary factor leading to neonatal death, particularly prior to neonatal biomedical care, is inadequate growth and development. The sensitivity of this period is widely recognized across cultures and illustrated by the institution of a 4–6 week postnatal rest period. Such a rest period allows the mother and infant to rest, bond, and establish breastfeeding. Visitations are typically kept to a minimum; thus, this postnatal rest period can also serve to limit exposure to pathogens or other causes of illness, such as the evil eye. During this period, the mother is given foods culturally understood to foster breast milk production and recovery from birth (more on feeding the mother in the adulthood section). The feasibility of the postnatal rest period is influenced by family structure (e.g., presence of kin to care for the mother and newborn as well as the rest of the household), socioeconomic status, and political-economic policies (e.g., availability of paid or even unpaid maternal leave).

One issue where Western biomedical/nutritional knowledge has diverged with traditional

newborn feeding practices in many cultures globally is the practice of not breastfeeding the neonate until approximately 3 days after birth, when the milk has come in. The golden-hued liquid, colostrum, first produced is considered a critical source of nutrients and antibodies fashioned in an easily digestible form in contemporary biomedical contexts. However, in places where colostrum is avoided, other liquids may be fed to the newborn, such as water sweetened with honey or sugar. Various reasons have been reported for this, including the colostrum is impure and perceived as “pus-like” or as diluted milk and in turn can cause indigestion or other health problems in the infant. However, from a biomedical perspective, colostrum avoidance is problematic, for not only are the antibodies and nutrients not transmitted, but the water or the tools used to feed the neonate, such as a rag or sponge with which drops of the sweetened water are squeezed into the newborn’s mouth, may transmit pathogens. Furthermore, the newborn’s suckling reflex is undermined when breastfeeding is not initiated shortly after birth, and this can lead to ongoing challenges in breastfeeding (note that this is echoed in hospital deliveries, when the newborn is separated from the mother). Various biomedically informed education efforts around the world have been effective in reducing colostrum avoidance, but people may still feed the neonate sweetened water when doing so has strong culturally symbolic meanings, such as blessings for a long, happy life. For example, infants may be breastfed before the milk is let down but in conjunction with sweetened water. This indicates the importance of symbolic, cultural meanings of a feeding practice.

Infancy is defined as beginning at the second month of life and ending at weaning, typically the first 3 years of life (Bogin 2001, pp. 77–81). Infant feeding practices and debates have centered on breast versus bottle/formula, social support for breastfeeding, length of time for exclusive breastfeeding and introduction of solid foods, and age of weaning. How breastfeeding is practiced is not uniform across individuals or cultures. On-demand breastfeeding, where the infant feeds whenever and for however long she or he desires,

requires specific maternal/family behaviors, including co-sleeping, carrying or keeping the infant close-by, clothing that allows for ease of breastfeeding while conforming to local modesty mores, and social/family support for breastfeeding. Feeding on a schedule, oftentimes dictated by other demands on the mother’s time, can accommodate a wider variety of behaviors and practices, including sleeping arrangements.

“Breast is best” is a refrain common in contemporary public discourse, as the biological and behavioral benefits of breastfeeding, for both infant and mother, have been recognized and promulgated by various health organizations and breastfeeding advocates. There has been a long-standing polarization between breastfeeding advocates and infant formula manufacturers, dating back to the first half of the twentieth century. From this period, infant formula became increasingly socially accepted and practiced, with a concurrent decline in the support and practice of breastfeeding. Feeding one’s infant with breast milk or infant formula was classed, as higher social status women, who had the means to purchase formula, bottles, etc., shifted to formula feeding first. Choosing to breast-feed in this environment was difficult, and those women came together to form support groups like the La Leche League. Because of the social prestige and assumed technological benefits associated with formula, women of lower social status throughout the world began to shift to formula feeding. However, to cope with the costs associated with formula feeding, these women came up with a variety of strategies to provide the benefits of formula feeding, such as diluting the formula. Furthermore, the water used was too often unsanitary and, combined with the lack of antibodies provided in breast milk, resulted in greater chances of illness in infants. As recognition of these problems increased globally, various groups agitated against formula feeding and culminated in the globally publicized anti-Nestle campaigns and resultant trial in the early 1970s. Consumer boycotts and education campaigns have increased since then, resulting in a shift in infant feeding practices, where more women of higher social strata now breast-feed (Van Esterik 1995). Efforts to foster breastfeeding continue by

providing lactation specialists and support both in hospital and at home and limiting exposure to formula in hospitals, through efforts like the Baby-Friendly Hospital Initiative of 1991 (WHO and UNICEF 2009).

Current biomedical recommendations promote exclusive breastfeeding for 6 months and continuation of breastfeeding for 2 years or beyond. For women to follow these recommendations, the sociocultural contexts in which they live must provide a milieu that is supportive of those recommendations. Not only is familial/social support for the mother necessary, but so are workplace environments and political-economic policies that can accommodate mothers who breast-feed their infants. For example, in a global survey of 188 countries, approximately 96% provided paid maternal leave, while over half offered 14 or more paid weeks. Furthermore, 75% of the countries surveyed ($N = 181$ with data) protected women's right to breast-feed at work. Recent information indicates the majority of countries guarantee paid breastfeeding breaks (Heymann 2012, Chap. 5; Heymann et al. 2013). Thus, countries that do not provide legislation and policies that support paid maternal leave and breastfeeding create an inequitable infant feeding environment so that only mothers who have the economic means to take maternal leave can afford to initiate and exclusively breast-feed for 6 months, if they choose to breast-feed. It must be remembered that not all women can or want to breast-feed, for a variety of reasons, and the acceptability of these choices has altered across time and space. The infant feeding practices a woman utilizes not only are reflective of her choices, knowledge, and preferences but are shaped by her sociocultural and political-economic contexts. More work is needed on how women integrate multiple infant feeding practices across cultures and in different social milieus.

The politics of weaning is intertwined with the political-economic context of breastfeeding, for many mothers will cease breastfeeding at the end of the maternal leave. Ethnographic evidence suggests that the typical age of weaning for most of human history was approximately 2–3 years, coincident with the emergence of a child's deciduous dentition. Yet it is clear that there is a wide

variation in age of weaning, both between and within cultural groups. Contemporary lack of social support for breastfeeding for toddlers in the United States does not mean that it does not happen; "secretive nursing" of older children occurs, where women do not reveal this practice even to their health practitioners (Dettwyler 1995).

Childhood and Juvenile

Weaning marks the transition to childhood, from approximately 3 years until the age of seven, and is characterized by particular feeding needs based on biology. First, deciduous dentition combined with a relatively small digestive system means that a child ought to be fed foods that are easily chewed and digested and low in volume. Second, because of the relatively large brain of a child and the associated high metabolic costs, foods need to be nutrient-dense. Third, children's cognitive and motor skills are not adequate for them to acquire and prepare foods, and so they remain dependent on older individuals (Bogin 2001, pp. 81–84). The juvenile period, from the age of seven until puberty, is marked by the ability to process an adult-type diet (coincident with the eruption of the adult dentition, beginning with the permanent molar) and a decrease in the high nutrient needs associated with brain growth, as growth, in terms of weight, is completed. Development in motor and cognitive skills has advanced so that a juvenile is able to rely less on older individuals and to feed themselves (Bogin 2001, pp. 83–87). Yet socially, a juvenile remains dependent on others. For the remainder of this section, the term children will be used.

There are a number of ethical issues related to feeding children; here, the preferential feeding of children is based on gender. The most common gendered preferential feeding practices are those favoring sons while neglecting daughters. Girls may be weaned earlier and receive less food and/or poorer-quality foods (or not be offered "special" foods or treats). Son preference has been described in a variety of societies, but it is important to recognize the variation within and between cultural groups. For example, in a study in rural Mexico, dietary quality was equitable

among children, whereas girls consumed less; however, the researchers noted that girls were less active (fitting gender norms on girls' ideal behavior – quiet and demure), as determined in playground observations, and so required fewer calories (Backstrand et al. 1997). In contrast, in rural Bangladesh, girls are weaned earlier and receive a third less rice than their brothers (Ahmed and Zeitlin 1994). A variety of studies undertaken in South Asia have documented that son preference and daughter neglect feeding practices are regionally distributed and have changed over time. Furthermore, family composition is associated with daughter neglect feeding practices; birth order and the gender of older siblings affect this practice, for daughters *are* desired. Thus, a firstborn daughter has a much lower risk of neglect with respect to feeding practices. It should also be noted that although the focus here has been on gendered feeding practices of children, health-care allocation is another important factor shaping gendered childhood differentials in morbidity and mortality.

Adolescence

Adolescence initiates with puberty, ending with cessation of growth. There are changes not only in body size but also in body shape; typically this pattern is gendered, as boys have a relative increase in muscle mass, while girls show a relative increase in body fat (Bogin 2001, pp. 87–93). These physical changes in combination with societal norms of desirable, gendered bodies can create particular eating issues. For example, in some cultural groups, a large body size in women is viewed as desirable, and so girls' eating practices will be controlled in order to attain that desired body size. This involves eating even when the girl does not wish to, being fed specific foods that are culturally understood to foster increased size, as well as limiting physical movements. It is not an easy process; girls may cry and resist, and older women recognize this as “work” – it takes great effort to attain the ideal (Popenoe 2004).

In contrast, in North America, the opposite ideal, of a skinny body, has long been the norm

for girls and women (Grogan 2008). Dissatisfaction with one's own body, particularly weight, manifests in adolescence – studies report that 66% of adolescent girls are dissatisfied with their body weight and over half are dissatisfied with the shape of their bodies, particularly the size of their thighs, buttocks, and hips (e.g., Moore 1993). This dissatisfaction manifests in disordered eating practices, including dieting, fasting, purging, etc. Yet the causal relationship between media portrayals, body dissatisfaction, and disordered eating is not clear (Levine and Murnen 2009). This is an important issue to continue to investigate, not only in North America but also globally, as Hollywood and other forms of Western media are consumed in diverse cultural settings (e.g., Shroff and Thompson 2004), in conjunction with global concerns around obesity. Furthermore, the unique experiences of boys need continued investigation, for body dissatisfaction has been noted, in particular in relation to perceived low muscle mass/size, as the hyper-muscular, lean male body has increasingly been idealized (Botta 2003; Moore 1993). Disordered eating practices can result – although with a different objective – to increase muscle mass and muscle visibility. Because adolescents continue to grow and develop, disordered eating practices can have lifelong consequences.

Adulthood

Adulthood is more difficult to define, in that the end comes with the end of childbearing years – menopause – for women, but more challenging to define in men (Bogin 2001). This definition focuses on fertility and reproduction, and in keeping with this definition, issues arising with pregnancy are focused upon here. This discussion will also be linked with the prenatal life stage, for oftentimes discourses on women's diet during pregnancy are centered on how her eating habits shape the biology and welfare of the fetus.

How much women eat while pregnant is culturally mediated, for although there are some increases in nutrient/caloric requirements, these are not very large. Biomedical discourse, in the context of the “obesity epidemic,” emphasizes

that little weight gain is necessary for a healthy baby and gaining too much weight may lead to birth complications and health problems for the infant and mother. Research suggests that if the mother's diet is low in energy, protein, and micro-nutrients, then her child has an increased risk of obesity in adulthood, and their daughters are more vulnerable than their sons (Yang and Huffman 2013). Pregnancy weight gain guidelines are linked with body mass index, where weight is understood in relation to height; note that not gaining enough weight if the mother is underweight at the start of the pregnancy is also a health risk. But separate from biomedical guidelines are traditional guidelines, such as "eating for two" or limiting food consumption so that the fetus has room to grow (e.g., Nichter and Nichter 1983). Thus, regardless of women's body size prior to pregnancy, if she and her family believe that she must limit or increase her intake to ensure a healthy baby, then biomedical advice may be ignored.

Food taboos shape pregnant women's food practices across time and space, from avoidance of alcohol and caffeine in North America to "hot" foods across cultures with humoral medical systems. These taboos are framed as practices necessary to protect the health of the fetus. For example, consumption of "hot" foods is a cause of miscarriage. Typically, these food taboos do not restrict carbohydrate dietary staples, but rather restrict protein sources such as meat or eggs and/or some fruits and vegetables. Consequently, dietary quality may be affected. In some cases, taboos may so restrict eating practices that women's nutritional health may be affected, especially if combined with pregnancy sickness.

Also shaping adult eating practices are gendered understandings of body and food. Men, across historical and cultural contexts that emphasize their economic role in the family, may be understood to require more, and heartier, food compared to adult women. Such beliefs shape not only what people eat but how men and women socialize over food: women may wait to eat until men have had their fill or purposely snack prior to a meal in order to not eat heartily in front of their male date (e.g., Counihan 1992).

Elderhood and Senescence

The biological experience of elderhood and senescence is challenging to describe, for it is a highly idiosyncratic process. It is a process of decline, but molecular or other physical changes seen in one individual are not necessarily evident in another (Bogin 2001, pp. 95–97). One common experience in old age is a decline in abilities to taste and smell, which can lead to a decreased variation in diet and, in turn, a decline in nutrient intake. Loneliness and culinary knowledge can also shape eating behaviors during old age, and this is gendered, with older men exhibiting poorer diets. Furthermore, consequences of early life eating behaviors, such as dieting in adolescence, may affect experiences of aging and wellness.

Cultural gender norms continue to influence older women's eating practices, with some women striving for a youthful, thin body, which in turn can lead to disordered eating (or continued patterns of disordered eating from earlier life stages). However, with aging, a greater acceptance of various, particularly larger, body types has been noted, especially when weight gain is viewed as an inevitable experience of aging. Such a belief could be freeing, as women no longer worried about the thin ideal and dieting; thus aging can be freeing. Less is known about older men's body image and associated eating behaviors, although it is suggested that men as a group continue to suffer less body dissatisfaction and an opposite pressure – to maintain muscle mass (Peat et al. 2008). Further research is also needed on potential cohort's variable eating practices and experiences.

Summary

Eating behaviors and feeding practices across the human lifespan are the result of biological requirements and cultural customs. Ethical issues arise within all life stages, and gender identity and cultural norms are an important factor in shaping eating and feeding practices. Although discussed here with respect to each life stage, it is important to recognize the lifelong

and potential intergenerational effects of food practices. A girl child who is neglected from birth, who may be fed less frequently, weaned early, and given less food or poorer-quality food compared to her brothers or elder siblings, will suffer in terms of her growth and development, and this can have lifelong consequences. Furthermore, evidence is accruing that the experiences of the mother may have biological consequences for not only her children but also her grandchildren. Simultaneously, there must be awareness of the social, cultural, and environmental contexts that shape feeding practices of mothers and do not place sole responsibility on mothers for the eating behaviors of their children.

Introduction

Ecofeminism rose to prominence in the 1980s as an intersectional offshoot of academic feminism and the social justice and environmental movements of the 1960s and 1970s. It is notoriously resistant to succinct definition. Various called “ecofeminist philosophy,” “ecological feminism,” “feminist environmentalism,” and “critical feminist eco-socialist analysis,” ecofeminism is not a monolithic discipline but an assemblage of manifold feminist approaches to diverse ecological problems (Gaard 2011, p. 38). There are at least as many perspectives within ecofeminism as there are within feminism, and not all texts justifiably described as ecofeminist are so labeled by their authors. In most cases, the common thread is the assumption that there is an isomorphic relationship between the conceptual structures underlying the domination of women and the domination of nature. In her classic essay “The Power and Promise of Ecofeminism,” Karen Warren argues that these structures are supported by the “logic of domination,” a mechanism that, on the basis of patriarchal and dualistic “value-hierarchical thinking,” authorizes and maintains the subordination of the hierarchically inferior by the hierarchically superior (e.g., masculine/feminine, human/nature); while the attribution of inferiority is often but not necessarily objectionable in itself, the logic of domination is problematic because it assumes this attribution to be a sufficient premise for subordination (Warren 1990, p. 128). Thus, in ecofeminism there is a critical emphasis not only upon specific cases of oppression but also upon the structure of oppression itself. This emphasis gives rise to a frequently foregrounded “opposition to all forms of oppression”; integrated within its analyses there is often critique of other forms of injustice, e.g., speciesism, colonialism, ethnocentrism, racism, classism, and heterosexism (Plumwood 2000, p. 287). (For a historical overview of ecofeminism, see Cuomo 1996; Gaard 2011).

Some contend that in the last decade, ecofeminism has become somewhat passé in the wake of accusations of essentialism from other feminists (Gaard 2011, pp. 26–7). However, as ecofeminist Greta Gaard argues, these accusations myopically

focus on those early forms of cultural ecofeminism that propose an uncritical binary value reversal of feminine goddess spirituality over patriarchy, thus unfairly neglecting “ecofeminism’s diversity of argument and standpoint” (Gaard 2011, p. 31). In addition to its ongoing relevance to the still deepening ecological crisis, ecofeminism is particularly important in the context of increasing feminist interest in animals and food, each topics of recent or upcoming special issues of leading feminist journals *Hypatia* (27.3 “Animal Others,” 2012) and the *International Journal of Feminist Approaches to Bioethics* (8.2 “Just Food,” 2014).

This necessarily selective essay aims to illustrate the vast stylistic and thematic diversity of ecofeminist approaches to food ethics. There follows a discussion of three important approaches: (I) Vandana Shiva’s postdevelopment ecofeminist critique of global industrial agriculture and biotechnology; (II) vegetarian ecofeminism’s critical perspectives on mainstream animal liberation, culminating here in Val Plumwood’s synthesis of key internal debates; and (III) Eva-Maria Simms’s recent phenomenological analysis of the edibility of the maternal body – a new area in ecofeminist thinking about food – and its implications for our orientation to the environmental impact of food choices.

Ecofeminism and Global Agricultural and Biotechnological Development

Vandana Shiva’s ecofeminism is a multidisciplinary, activism-oriented theory engaged at the level of the global politics and economics of industrial agricultural development. Her approach grows from her lifelong connection to nature and to food production in Northern India. Raised in the Himalayan foothills by a farmer mother and conservationist father, she involved herself as a young student in the 1970s with the women of the Chipko movement, the original tree huggers. While subsequently earning degrees in physics and in the philosophy of physics, she became concerned about the health and environmental effects of nuclear radiation and other technologies. This concern led her to launch in 1982 the

Research Foundation for Science, Technology, and Ecology, which seeks to put research at the service of grassroots movements. One of her major projects with the foundation was to establish, in 1991, the organic farming organization Navdanya (“Nine Seeds”) in order to promote food security in India and, more specifically, to set up local seed banks across the country as a way to safeguard the diversity of India’s biological and cultural resources against corporate encroachment.

Throughout her prolific written work, which integrates this rich background of life experience, Shiva proposes a multi-systems critique of global agricultural and biotechnological development in India and the Global South. Informed by geology, sociology, plant physiology, and economics (among other disciplines), and deploying ecofeminism’s sensitivity to the interconnections among forms of oppression, she argues that such development creates, in the same gesture, the material oppression of nature and humans, especially woman. In her critical analysis, problems of food security, environmental degradation, agricultural labor autonomy, and economic and cultural colonization are understood as intertwined phenomena.

Development as Maldevelopment and Gender-Based Ideology

At the core of Shiva’s classic text *Staying Alive* (1989) is the claim that the purportedly post-colonial Western “development” paradigm is in fact a further advancement of colonialism. Development, she says, is really “maldevelopment”: in creating wealth for the developers, it creates poverty for the developed (Shiva 1989, p. 5). The hidden costs of such development are borne primarily by nature and by women, who are, as Shiva points out, the primary food producers in a clear statistical majority of cases in the rural Global South. Distinguishing “culturally perceived poverty” from “real material poverty,” Shiva argues that what developmentalism perceives as poverty is in fact subsistence living, a practice in which (typically) women have traditionally “partnered” with nature’s productivity to provide food in a way that “ensures the sustainability of

sustenance” (Shiva 1989, pp. 9, 45). The aim of subsistence living is not surplus but just enough for healthy living. Falsely identifying this “just enough” as poverty in need of rescue, and replacing traditional methods with those of large-scale, profit-driven agriculture, development creates “real material poverty.” Land and water resources are diverted from sustenance needs and channeled into the production of cash crops and other market commodities. Where a harmonious relationship between nature and food producers once yielded adequate sustenance for survival, there came famine, divestment of traditional land-use rights and economic autonomy, rural impoverishment, massive debt to colonial lenders, damned rivers, and soil erosion.

Of particular concern to Shiva is developmentalism’s denigration of the traditional empirical knowledge of woman farmers, whose sustainable methods are sensitive to nature’s cycles and interconnectedness. Developmentalism imports a “gender-based ideology,” she says, that relies upon a “fragmented, reductionist, dualist perspective” (Shiva 1989, pp. xv, 5). This perspective “violates the integrity and harmony of [humans] in nature and the harmony between men and women” by categorizing nature and women as passive, compartmentalizable resources (Shiva 1989, p. 5). Shiva writes:

The forest is separated from the river, the field is separated from the forest, the animals are separated from the crops. Each is then separately developed, and the delicate balance which ensures sustainability and equity is destroyed. The visibility of dramatic breaks and ruptures is posited as ‘progress’. Marginalized women are either dispensed with or colonized. Needs go unfulfilled, nature is crippled. (Shiva 1989, p. 45)

Colonization of Seed

For Shiva, the compartmentalizing tactics and renewed colonialism of developmentalism reach a peak in the commodification and colonization of seed itself, “the first link in the food chain” (Shiva 1989, p. 115). Here, developmentalism strikes the heart of nature and human life. The so-called Green Revolution, claimed by its proponents to have flourished in Punjab’s agricultural economy

and subsequently elsewhere in the Global South, was supposed to have made great advances in food security for the ever-increasing population thanks to Norman Borlaug's Nobel Prize-winning hybridized, high-yielding "miracle" seeds (Shiva 1989, p. 115). However, in *Staying Alive* and *The Violence of the Green Revolution* (1991), Shiva initiates a lifelong critique of this biotechnological innovation and the multinational corporate tactics by which it was deployed, such as privatizing seed through intellectual property rights. "The social and political planning that went into the Green Revolution aimed at engineering not just seeds but social relations as well," she says (Shiva 1991, p. 16). Whereas the peasant women of India had "over millennia" safeguarded "the self-reproducing character and genetic diversity of seeds," the incursion of patented, nonrenewable seeds transformed sustainable local farms into foreign-controlled factory fields for monoculture crops. This event exacerbated the economic subservience of less wealthy nations, both to Western corporate "innovators" and to the World Bank loans that subsidized seed distribution (Shiva 2009, pp. 24, 21, 22). If peasant farmers now must purchase new supplies of the nonrenewable hybrid seeds each year, then the miracle of "miracle seeds" is really a "commercial miracle" that draws the Global South deep into the Western agribusiness market (Shiva 1989, p. 116). Thus, as seed is divested of its natural fertility, women farmers are divested of their traditional role as stewards of biodiversity and sustainability. Moreover, the toxic pesticides and fertilizers required by hybrid seeds devastate native plants and desiccate soils.

Prakriti: The Feminine Principle

Thus, for Shiva, the operative assumption behind the tactics of agricultural and biotechnological "maldevelopment" is that nature and women are unproductive, that "'production' takes place only when mediated by technologies for commodity production, even when such technologies destroy life" (Shiva 1989, p. 3). As a solution, she proposes the recovery of Prakriti, the "feminine principle" of the "ancient [Hindu] worldview," which recognizes nature and women as the "creators and

sustainers of life" (Shiva 1989, pp. xv, 5). As distinct from the alleged Western categorization of femininity and nature as passive, Prakriti is a creative "living force that supports life," the very source of the biodiversity and self-renewability that Borlaug's hybrid seeds deny (Shiva 1989, p. xv). Participation in Prakriti, which ultimately "transcends gender," is equally open to men, but when "productive" man is "alienated" from Prakriti's original productivity, the primal activity of life is reduced to hypermasculine "domination" of man over nature and women (Shiva 1989, pp. xv, 5). For Shiva, maldevelopment is one symptom of such a reduction. Taking inspiration from the Chipko women, she locates in Prakriti an alternate "concept of economics as production of sustenance and needs satisfaction" that challenges the "Western concept of economics as production of profits and capital accumulation" (Shiva 1989, p. xv). Exposing "what patriarchy sees as productive work" to be highly *destructive*, Prakriti shows life itself to be the source of productivity (Shiva 1989, p. 8). From the Prakriti perspective, nature does not oppose economics, but *is* economics at its origin.

Shiva's use of Prakriti has been criticized as expressing a naïve or essentialist interpretation of the feminine and, in its application to the experiential knowledge of peasant women, as promoting an uncritical standpoint epistemology. However, as Shiva's critic Ariel Salleh points out, Prakriti retains some strategic value if taken as an "oppositional term in a process of ideological deconstruction" grounded not in speculation about essences but in commonly shared experiences (Salleh 1991, p. 212). In this light, one may see Prakriti as a challenge to developmentalism's "Cartesian split between human labor and nature" that arises from within the perspective of Indian women farmers' traditional "partnership" with nature (Salleh 1991, p. 214).

Vegetarian Ecofeminism and Animal Liberation

Whereas Shiva's postdevelopment ecofeminism offers multidisciplinary analyses of the interconnected oppression of nature and women

in the Global South, the area of ecofeminism referred to as “vegetarian ecofeminism” or “animal ecofeminism” engages specific philosophical problems of animal liberation originally raised in the context of applied ethics and largely ignored by early ecofeminists. According to Gaard, the “fundamental insight” of vegetarian ecofeminism is that speciesism – the arbitrary preference of one’s own species over another in a manner analogous to sexism or racism – is a “form of oppression that is interconnected with and reinforcing of other oppressive structures” (Gaard 2000, p. 206). To exclude species oppression from ecofeminist theory is both to risk incomplete analysis and to contravene ecofeminism’s “activist and philosophical foundations” (Gaard 2002, p. 130). Thus, despite opposition from other feminists (e.g., George 1994; Stange 1997), vegetarian ecofeminists use ecofeminist rubrics to address problems of animal liberation such as industrial animal food production, hunting, social conceptions of meat, and the reconciliation of vegetarianism with questions of social and environmental justice. The contributions of three important vegetarian ecofeminists, Carol Adams, Lori Gruen, and Val Plumwood, are discussed below.

Bringing Animals into Ecofeminism

The radical-cultural feminist Carol Adams was among the first feminist writers to bring together animal liberation and ecofeminism (also see Kheel 1991). Known for *The Sexual Politics of Meat* (1990), which aims to highlight the twin cultural phenomena of the sexualization of meat consumption and the animalization of women, Adams advances ecofeminist arguments for vegetarianism and veganism in “Ecofeminism and the Eating of Animals” (1991) and again in “Why Feminist-Vegan Now?” (2010). Identifying a blatant disregard for animal welfare among early ecofeminists, whose attention lay primarily with the earth and its ecosystems, Adams locates several perspectives *within* ecofeminism that imply vegetarianism and ultimately, for Adams, a strict universal veganism (Adams 1991, pp. 125, 141). Four are discussed here.

Corporeally Imaginative Identification

Recognizing the links between the domination of women and nature, and heeding Warren’s ecofeminist call to critique the underlying hierarchical “logic of domination,” Adams proposes a “radical feminist epistemology” that produces an imaginative “identification” with the bodies of animals as victims of exploitation (Adams 1991, p. 128). Feminists recognize and identify with the painful experience of being objectified and instrumentalized as women – as “pieces of meat,” for example. For Adams, such recognition undercuts the human/animal hierarchy and establishes compelling sympathies toward animals as living sentient beings. Such sympathies preclude any need to “accede rights” to animals and render abhorrent the idea of instrumentalizing animals for food (Adams 1991, p. 129).

Reintegration of the Ecological Consequences of Meat-Eating

Adams argues that if ecofeminists oppose the domination of the earth, then they must also oppose meat production, which has measurable and well-known consequences for the health of the natural environment (e.g., the high demand on water and energy in raising and distributing livestock; large-scale topsoil erosion caused by grazing). The frequent conceptual isolation of meat-eating from its detrimental consequences, says Adams, results from two of the reductive, patriarchal dualisms that ecofeminism contests, namely, consumption/production and production/maintenance (Adams 1991, p. 130). The dismantling of these dualisms belongs already to the ecofeminist mandate. Ecofeminism thus implies that the consumption of meat as a product and economic “good” should not be viewed as separate from or more highly valued than the conditions of its production (which entail suffering and death for animals and frequently poor conditions for workers, who are often women) or the ongoing maintenance required to sustain the land that supports the meat industry.

Social Construction of Bodies

It might be objected that the basic ecofeminist (and environmentalist) premise that humans are

natural beings implies that our meat-eating is “naturally” justifiable. Adams counters that, insofar as it is a critique of the structures of oppression, ecofeminism is positioned to support vegetarianism by means of a critical examination of the modes of subjugation involved in the social construction of meaning. She points out that our everyday language obscures and therefore perpetuates hierarchical and oppressive ideologies of both women and animals. As the term “battered women” reflects and sustains an “ontologization” of women’s bodies as sexually consumable, so the term “meat” reflects and sustains an ontologization of animal bodies as edible (Adams 1991, p. 136). In this way, women and animals are positioned as objects, thus concealing the subject and perpetrator of violence and rendering the “being” of women and animals as what Adams calls an “absent referent.” The violence inflicted upon women and animals is tacitly interpreted as something that is part of their nature. “Live animals are the absent referents in the concept of meat. The absent referent permits us to forget about the animal as an independent entity, . . . to resist efforts to make animals present, . . . to allow for the moral abandonment of a being” (Adams 2010, p. 304). To the extent that ecofeminism is attentive to the oppressive hierarchies obscured by language, it is in a position to resist the sociolinguistic construction of animals as meat and humans as carnivores.

Critique of Autonomy

In response to the potential objection that an ecofeminist call for vegetarianism would violate a person’s autonomy in choosing what to eat, Adams suggests that the ecofeminist eschewal of the reductive individualism of rights-based thinking invites us to think of ourselves in relationship to animals – by, for example, identifying with and thus engendering solidarity with animals. For Adams, to eat animals is to instrumentalize them and to thus affirm and propagate the dualistic ideology of domination that ecofeminism aims to eradicate. The more appropriate kind of autonomy is achieved, she suggests, by “acting independently of such ideology” (Adams 1991, p. 140).

The Ecofeminist Critique of Mainstream Animal Liberation Theory

While Carol Adams has offered a critical reappraisal of ecofeminism in order to include animal liberation within its agenda, other vegetarian ecofeminists have critiqued and offered corrections to the influential animal liberation theories of Peter Singer and Tom Regan, each of which prescribes vegetarianism or substantial limitations on meat-eating (see Gruen 1993; Kheel 1996; Plumwood 1991; Luke 1995; see also Donovan 1990). In “Dismantling Oppression: An Analysis of the Connection Between Women and Animals,” ecofeminist Lori Gruen takes Singer and Regan to task for their exclusive emphasis on reason and individualism in moral deliberation. Briefly stated, Singer’s utilitarian defense of nonhuman animals argues that since *any* sentient being can suffer and thus has “interests,” in moral deliberations these interests must be given “equal consideration” (Singer 1975, p. 8). Proceeding otherwise would perpetrate speciesism. Regan’s rights-based deontological approach, by contrast, takes self-consciousness as the criterion of moral consideration. All “subjects-of-a-life,” or self-conscious beings, possess inherent value, which admits no comparison and is therefore always possessed equally (Regan 1985, p. 23). Thus, even if, like human infants or people with a serious developmental disability, their moral agency is absent or lacking, all self-conscious animals (adult mammals, at least) are entitled to be treated equally as moral patients on the basis of their inherent value, which ought to be protected by a right.

Although Gruen generally supports the goals of animal liberation theory, she detects in both Singer and Regan a dubious privileging of reason over emotion: “reason – not emotion – compels us to recognize the equivalent value of certain animals,” says Regan, and “the application of these [utilitarian] principles [to animals] is demanded by reason, not emotion,” says Singer (Regan 1985, p. 24; Singer 1975, pp. ix–x). For Gruen, this position is problematic for two interrelated reasons. (1) The reason/emotion dichotomy is a “normative dualism that gives rise to the logic of domination” and thus permits “the continued

conceptualization of hierarchies in which a theoretically privileged group or way of thinking is superior” – in this case, reason (Gruen 1993, pp. 79–80). The obvious problem here, Gruen says, is that “by establishing superiority in theory the groundwork is laid for oppression of the inferior in practice” (Gruen 1993, p. 80). Thus, the rights and utilitarian principles invoked by Regan and Singer serve as little more than checks on an already hierarchical system that values humans over animals and reason over emotion; nature’s interconnectedness goes unacknowledged and the place of animals must be annexed by argument. (2) In its focus on reason, claims Gruen, traditional animal liberation theory is a methodologically incomplete theory. Ecofeminism, by contrast, “recognizes sympathy and compassion as fundamental features of any inclusive, liberatory theory” (Gruen 1993, p. 80). Not only are these emotions strategically necessary for “undoing oppression in both theory and practice,” but moral deliberation about animals requires “the emotional force of kinship” – something that arises, Gruen suggests, from within the ecofeminist experience of the earth as a nonhierarchical community. To the extent that the theories of Singer and Regan remain abstract, they perpetuate “our removal from the animals themselves” and fail to motivate attitude change (Gruen 1993, p. 79).

Plumwood’s Integrated and Contextual Moral Vegetarianism

In her approach to questions of vegetarianism and veganism, Australian environmental activist and feminist philosopher Val Plumwood (1939–2008) seeks to reconcile the often conflicting perspectives of animal liberation theory, holistic ecological theory, feminism, and social justice with a particular sensitivity to problems of ecological alienation, anthropocentrism, ethnocentrism, and activist strategy. In her classic text *Feminism and the Mastery of Nature* (1993), Plumwood argues for a version of the ecofeminist thesis articulated by Warren. She identifies a fundamental reason/nature dualism underlying a basic “master model” that both (1) interlinks the oppression of whatever groups this dualism allows to be constructed as

inferior – animals, women, and indigenous people, for example – and (2) denies “dependency and community” in our relations with others and with nature (Plumwood 1993, pp. 23, 194).

The Critique of Moral Extensionism

It is from this critical perspective that Plumwood, like Gruen, faults conventional vegetarian and animal liberation theories. She shares Gruen’s concern about the emphasis on “separation and autonomy” in rights-based theories such as Regan’s and the corresponding exclusion of “less dualistic moral concepts” (e.g., “respect, sympathy, care, concern, compassion, gratitude, friendship, and responsibility”) (Plumwood 1991, p. 8). But Plumwood also develops a critique of moral extensionism as such, the status quo practice in academic environmental ethics in which traditional ethical theories are applied or “extended” to accommodate nonhuman beings and entities. Such a practice, she says, is an “approach of minimal departure from the rationalist foundation of liberal humanism” (Plumwood 2000, p. 286). In its focus on regulating the acceptance of nonhuman animals into the sphere of moral consideration, typically “entirely on the basis of their similarity to the human,” moral extensionism neither considers the viability of anthropocentric ethics and epistemology for nonhuman moral patients nor asks whether there might be modes of attention and responsibility that are preempted by the exclusionism that remains in any extensionist project (Plumwood 1998, p. 407). Any redrawing of the human/nature or human/animal boundaries implicitly reaffirms these boundaries, which ultimately serve to guard what Plumwood calls the “hyperseparation” from nature that authorizes attitudes of human superiority (Plumwood 1998, p. 406).

Humans as Food

In her famous essay “Being Prey,” which viscerally contradicts the “hyperseparation” latent in moral extensionism, Plumwood describes and interprets her near-death encounter with a predatory crocodile in Australia’s Kakadu National Park in 1985. Her account offers a surprising and profoundly sensitive expression of the sort of

sympathy, kinship, and imagination she, Gruen, Adams, and other ecofeminist philosophers wish to introduce into vegetarian and animal liberation theory. Plumwood's recollection of this horrific episode, in which the crocodile tore into the flesh of her legs and torso as it dragged her into a "death roll," resonated for her on a critical register. As the predator had serrated her body, so her reflection on this experience "ripped apart" her "subject-centered," "from the inside" view of the world – the same view that underlies the project of moral extensionism. Revealing a decentered view "from the outside," this was an experience of *being* food, of *being* edible (Plumwood 1996, pp. 42, 35). Plumwood describes its potential for moral conversion thus:

I glimpsed beyond my own realm a shockingly indifferent world of necessity in which I had no more significance than any other edible being. The thought, *This can't be happening to me, I'm a human being, not meat, I don't deserve this fate!* was one component of my terminal incredulity. (Plumwood 1996, p. 42)

In a subsequent version of the same essay, she writes,

It was a shocking reduction, from a complex human being to a mere piece of meat. Reflection has persuaded me that not just humans but any creature can make the same claim to be more than just food. We are edible, but we are also much more than edible. Respectful, ecological eating must recognize both of these things. (Plumwood 2002)

The status quo subject-centered concept of human identity dualistically positions humans as external and hierarchically superior to the food chain, "not as part of the feast in a chain of reciprocity but as external manipulators and masters of it" (Plumwood 2002). For Plumwood, this dualism enables the radical discontinuity between "the outrage we experience at the idea of a human being eaten" and our quotidian experience of eating animals (Plumwood 2002). "We may daily consume other animals by the billions, but we ourselves cannot be food for worms and certainly not meat for crocodiles" (Plumwood 1996, p. 42). On the other side of this "dualistic vision of human mastery of the planet" in which we humans are predators but never prey, the crocodile is demonized as a vile beast or, in the

"masculinist" interpretation that appeared in Australian tabloids, as a monstrous male rival attacking a helpless woman awaiting rescue from the male hero (Plumwood 1996, pp. 42, 40). (*Crocodile Dundee* was filmed in Kakadu shortly after Plumwood's encounter).

Violently refuting this dualism, Plumwood's story of crocodile predation on a human portrays a transformation of incredulity into edibility. Such transformation constitutes the basis of an imaginative ethical sympathy: like the crocodile, the human, too, experiences itself both as an animal who eats and as an edible animal with a claim to be more than edible. Plumwood's remarkable experience, which her story allows others to repeat imaginatively, invites a non-subject-centered view of self – a view of the self "from the outside" (Plumwood 1996, p. 35). For Plumwood, this view provides a glimpse of ourselves in our "ecological identity," as "part of the food chain, eater as well as eaten" (Plumwood 1996, p. 43). In this way, it opens onto a vegetarian ethic that, in contrast to the minimum change, aloofness and closure implied in subject-based moral extensionism, is rooted in radical sympathy and a felt sense of the continuity of life (Plumwood 1996, p. 44).

The Critique of Adams's "Ontological Vegetarianism"

Having come to see animals as "more than just food," Plumwood condemns "the reduction of animal lives in factory farming systems that treat them as living meat" (Plumwood 2002). However, she proposes no sweeping condemnation of predation or meat-eating such as we find in both mainstream animal liberation theory and in Adams's ecofeminist vegetarianism. In place of what she calls Adams's "ontological vegetarianism" or "ontological veganism". Plumwood thus advocates a *contextual* moral vegetarianism. While Adams and Plumwood agree that animals deserve moral consideration, Adams's ontological veganism adds the premise that "nothing morally considerable should ever be ontologized as edible or as available for use" (Plumwood 2000, p. 287).

Plumwood objects to this universalist premise because it supports Adams's characterization of

vegetarianism and veganism as a “politics of personal virtue and self-denial” implicitly modelled on sexual abstinence (due in part to Adams’s “genderized” account of meat-eating as a mode of masculine sexual aggression) (Plumwood 2000, p. 291). Plumwood sees this characterization as problematic for several reasons. (a) It fosters “highly polarized,” “over-individualized,” and “vanguardist” interpretations of vegetarianism as “moral purity” that “hinder the spread of vegetarian orientations” and “impede useful intermediate positions”; (b) distracts from the global, neoliberal “economic rationality” at the root of the systematic “atrocities daily committed against animals, especially in the factory farming framework”; and (c) remains insensitive to crucial differences in scale of animal suffering between factory farming and individual and cultural practices such as hunting (Plumwood 2000, p. 291). The neglect of these broader circumstances is further supported, says Plumwood, by Adams’s “cultural feminist proclivity to privilege explanations focused on men and masculinity,” as well as by her portrayal of her assessment as culturally universal, that is, as “an account of inevitable and timeless ethical features of human predation” rather than as “a culturally specific account of present commodity practices of animal food in certain rationalist-reductionist cultures which often model rational control and enslavement in genderized terms” (Plumwood 2000, pp. 288, 295). In Adams’s “genderizing and demonizing” of meat-eating, hunting, and other “predator identities,” Plumwood detects a neglect of our ecological embeddedness in the food chain, an ethnocentric dismissal of indigenous food practices, and an “uncritical reversal of western gender ideals” in which “factors other than [contemporary western] masculinity” are largely excluded from the critique of animal domination (Plumwood 2000, pp. 288, 289).

What Plumwood ultimately finds most objectionable in Adams’s universalist ontological vegetarianism is its core claim that moral considerability and edibility are mutually exclusive, which implies that to choose to use animals for food in any way is to deny that they deserve moral consideration. From Plumwood’s perspective, this

stark dichotomy enables alienated, reductionist attitudes about (a) animal food, (b) food generally, and (c) human ecological embodiment.

- (a) What Adams calls “meat” is a “culturally specific reductionist and commodity category” that deserves to be critiqued and resisted, but, due to her commitment to the edibility/moral considerability dichotomy, Adams crucially fails to acknowledge this cultural specificity (Plumwood 2000, p. 296). As a result, the animal consumption practices of a specific abusive culture “come to appear as inevitable aspects of animal food and human predation and consumption – which of course they are not” (Plumwood 2000, p. 296). In other words, since Adams recognizes no possibilities for animal food other than “meat,” she draws a “false contrast” between vegetarianism/veganism and cultural practices of animal reduction and domination, between “no use at all and ruthless use” (Plumwood 2000, p. 298).
- (b) In light of Adams’s edibility/moral considerability dichotomy, the status of being food comes to appear as necessarily and universally a debased one, so that food exists in a lower, premoral order and bears no ethical relevance (outside of the initial dualistic decision to exclude it from the order of the morally considerable). However, as Plumwood points out, this idea that “only those beneath ethical consideration can be food” is a significant “reason why factory farming is able to treat those whom we position as food as beyond and outside ethics” (Plumwood 2000, p. 296). Adams’s strategy is at cross purposes.
- (c) Conversely, the edibility/moral considerability dichotomy excludes humans from edibility. That is, so long as we conceive of ourselves as morally considerable (as we inevitably do), we deny our edibility, our ecologically embodied participation in the food chain, in the continuity and “exchange of life” in which all embodied beings are food for some other being (Plumwood 2000, p. 299). Such an exclusion inadvertently

reinstates the same dualistic separation of humans from nature and animals that is allegedly at the root of the food practices Adams critiques.

By contrast, applying the ecofeminist critique of dualism to food itself, Plumwood's contextual moral vegetarianism contests the alleged mutual exclusivity of moral considerability and edibility. While Plumwood maintains that "no being, human or nonhuman, should be ontologized reductively as meat," she argues that "we must all, humans included, be ontologized ecologically" as food (Plumwood 2000, p. 298). This ecological necessity grounds the human practice she calls "sacred eating," acknowledging the wisdom in indigenous approaches to food. In sacred eating, we humans are called to gain our food – even plant food – "in such a way as to acknowledge our kinship with those whom we make our food, which does not forget the more-than-food that every one of us is, and which positions us reciprocally as food for others" (Plumwood 2000, p. 303). In this way, Plumwood locates in sacred eating a reconciliation of edibility and moral considerability.

Summary of Vegetarian Ecofeminism Discussion

Three significant contributions of vegetarian ecofeminism have been discussed: Adams's argument that the early ecofeminist focus on the earth conceals and neglects ecofeminism's theoretical resources for vegetarianism and veganism; Gruen's and Plumwood's critiques of the unduly masculine and anthropocentric perspective of mainstream animal liberation theory; and Plumwood's attempt to rectify the alleged failure of both animal liberation theory and vegetarian ecofeminism to integrate concerns about animal welfare with competing concerns about, for example, ecosystem health, the place of humans in the food chain, and the food practices of indigenous peoples. As we have seen, moreover, Adams, Gruen, and Plumwood each advocate for an approach to animal liberation that, like the feminist ethics of care, renews the role of experience, relationality, and sympathy in our approach to moral questions.

Ecofeminism and the Maternal Body

Like Plumwood, Eva-Maria Simms locates great potential for moral imagination within the experience of human edibility. Unlike Plumwood, Simms focuses on a phenomenon that often escapes our notice due not to its rarity but to its ubiquity: matrotopy, the nourishing of the developing fetus and infant via the placenta and breast milk. In her essay "Eating One's Mother: Female Embodiment in a Toxic World" (2009), which takes its theoretical cues both from the phenomenological analyses of intercorporeality proposed by the French phenomenologist Maurice Merleau-Ponty (1908–1961) and Belgian feminist philosopher Luce Irigaray and from a diverse array of recent research in ecology, toxicology, endocrinology, and pediatrics, Simms does not explicitly assimilate her project to ecofeminist goals. However, beginning with the feminist concern that the "androcentric history of philosophy" neglects "female experience" and privileges "independence" and "self-enclosure" in its conceptualizations of self and world (as the Cartesian worldview typifies), Simms's intersectional project introduces the insights of feminist phenomenology of the maternal body into the question of the human relationship to the natural environment (Simms 2009, pp. 267, 276).

Specifically, Simms uses the image of the placenta – the only mammalian organ composed of cells from two organisms – to reposition the human body as both food and ecosystem and to then realign our responsibilities to each other and to the environment regarding the toxins we allow into our bodies. Her project is thus clearly ecofeminist in the traditional sense: granting the essential and inevitable role of metaphor in "creating new ways of thinking," and foregrounding the role of a specifically feminine metaphor in moral imagination, it proposes a critical intervention in the conceptualization of our relation to the natural environment in which the "androcentric" schemata of separation and individuality are countered and corrected by notions of continuity and integration (Simms 2009, p. 267). Yet Simms also expands the ecofeminist project by reflecting the primary concept of ecology – the

ecosystem – back upon the human: as the placental relationship is a metaphor for our relationship to the environment, so the ecosystem is a metaphor for the womb itself.

For Simms, the critical value of matrotropy has two sources: (a) it undermines conventional ideas about the human place in the food chain, and (b) it provides an ethically compelling figure for the thorough ecological integration of the human body.

(a) Recalling an old yellowing poster of the food chain whose arrows all “pointed at a muscular male silhouette at the top,” Simms claims that such an image “creates the illusion of a closed system that ends at the apex with the super predator who consumes the distillate of all below” (Simms 2009, pp. 264, 273). The reality, Simms points out, is that “man’s” infants are above him on the food chain, for infants’ food is produced by the female human body. The matrotropic relationship, says Simms, thus unseats the human as “the self-owned and self-contained apex of creation” (Simms 2009, p. 264). The female body is “open,” “a conduit for the next generation, a passage for others that stretches through time. There is no hierarchical top of the food chain: woman herself becomes food for her young. She is a link and an integrated element in the chain of those who eat and are eaten” (Simms 2009, p. 264).

(b) In undermining the hierarchical nature of the food chain, the maternal body not only deposes the general figure of “man” from the top of the food chain but also serves for Simms as an image for the ecological openness of the human body itself. First of all, claims Simms, the maternal body is ecologically open in a biological sense because it is both immediate environment for another body and a conduit for food from the broader environment: “the fetal ecosystem is nested in the ecosystem of the mother’s body, which is nested in the larger ecosystem of the earth” (Simms 2009, p. 273). Thus, as the nutrients the mother consumes in food, water and air are passed along to the infant, whatever toxins

are present in this elemental nourishment are similarly passed along (and in fact are *concentrated* by means of a process ecologists call “biomagnification”) (Simms 2009, p. 266). The extent of the integration of the bodies of mother and fetus is reflected in the placenta, which is a *shared* organ (and not, as physicians believed until the 1960s, an impermeable barrier protecting the fetus from harmful substances). For Simms, the recognition of this corporeal continuity gives rise to a “placental ethics” that does not “stop at the boundary of our skins” (Simms 2009, p. 265). What this means, first of all, is that out of care for their developing babies mothers have a vested interest in avoiding (and perhaps campaigning against) the increasing prevalence of environmental toxins in food, water, and air. On this basis, Simms’s placental ethics provides a rather obvious anthropocentric rationale for the detoxification of our environments and food systems.

And yet, perhaps more importantly, such a placental ethics also provides an analogy through which the human corporeal identity may be ecologized and integrated into the food chain. As the mother’s body is continuous with the infant via the placenta, so the human body is a “pass through” to its surrounding environment:

The substances that we take into our bodies do not stay there. The antibiotic I take for my sinus infection does not end existing as soon as it enters my stomach, even though we prescribe it as if it does. Through digestion, elimination, and our own death we return elements back into the natural environment which are then taken up by other living beings. What is true for mackerel and smelt is also true for us: we are part of the food chain. The ethical call that issues from this insight is the demand to move beyond individualism toward an ecological responsibility for the whole field of being and begin to understand ourselves and act as an integrated part. (Simms 2009, p. 274).

For Simms, the figure of the maternal body reminds us that the human body is not a black box; as mother and fetus are entwined in the placenta, so “the structures of the body are entwined with the structures of nature through air and food” (Simms 2009, p. 276). This analogy

therefore suggests a maternal ethics of care for the natural environment in which the natural and corporeally interconnected care the mother feels for her child becomes interposed in the broader relationship between humans and their environment. As the mother endeavors to become safely edible for her incubating child, so we, too, are asked to become food safe. In short, Simms proposes that the boundaries of the lived human body become relationally and affectively reoriented – maternalized – in order that, in considering the food and drugs we permit into our bodies, it becomes no longer possible to proceed with ecological indifference.

Summary

This entry has traversed a diverse selection of ecofeminist approaches to diverse questions in food ethics. It has also demonstrated unifying threads. In each case discussed, we have seen an emphasis on the interconnections among forms of oppression, a commitment to multidisciplinary methods, and an attentiveness to the critical potential of feminist viewpoints. From the perspective of postdevelopment critique, Shiva diagnoses the socio-ecological problems of global food production in terms of developmentalism's underlying gender-based ideology and elevates the empirical, labor-based knowledge of rural women farmers as a critical counterexample. From the perspective of the ethics of animal liberation, vegetarian ecofeminists address the question of using animals for food by critically engaging ecofeminist insights to broaden and rework the methodologies and conclusions of mainstream animal liberation theories. Val Plumwood attempts to surmount the weaknesses of animal liberation theory and strict vegetarian/vegan ecofeminism by integrating considerations of indigenous food practice and the ecology of the food chain. Finally, from the perspective of phenomenological feminism, Simms locates the edibility of the maternal body as an imaginative resource for reintegrating the human in the food chain and, on this basis, radically expanding our ethical relation to the environmental consequences of our food choices.

Food regimes; Global food economy; Globalization of agriculture and food; Political economy of agriculture and food

Introduction

Food systems – the web of relations through which human beings organize food provisioning and consumption – are the foundation of all societies. For most of human history, food systems were organized on a local or regional scale and were deeply embedded in the ecologies and cultures of particular times and places. Today, however, nearly all food systems are integrated, albeit to different degrees, into the international circuits of production and distribution of the capitalist global food economy. Although societies have engaged in long-distance food trade for millennia, the scale, scope, and logic of organization of today's global food economy differ radically from historical patterns. In the global food economy, food producers and consumers are more geographically and socially distant than ever

before, new technologies are revolutionizing food production, and the spread of tastes and cuisines is changing diets at an unprecedented rate. While many people rely on the abundance of relatively cheap industrial food produced by the global food system, many others are excluded from the bounty. Millions of people participate in the global food economy as food producers but under radically different conditions based on their place in the “food chains” organized by agri-food companies.

This entry examines how the emergence of a global food economy has given rise to ethical controversies such as hunger- and diet-related diseases, animal cruelty, ecological crisis, and the plight of small farmers. The first section provides some background to the political economy of agri-food systems. Next, the entry outlines the emergence and consolidation of the global food economy and the social and ecological dislocations it has wrought. The final section considers some of the countermovements that articulate an alternative set of social, ecological, and ethical ideals to those of the global food economy.

The Political Economy of Agriculture and Food

Political economy is a social science tradition that analyses the economic realm, in the broadest sense, as a field of social relations of power. Unlike neoclassical economics, political economy does not take for granted that markets and other economic processes operate according to their own logic. Rather, these processes are shaped by social actors with competing interests, resources, and interpretations of reality. The outcomes of these struggles have consequences for the distribution of resources, the nature and direction of development processes, and the organization and character of other social institutions. There is a normative dimension to most political economy perspectives, which consists of the assumption – sometimes implicit – that social justice demands a broadly democratic control of economic institutions and an equitable distribution of resources.

The political economy of agriculture and food perspective emerged from a critical reappraisal of rural sociology in the late 1970s. At this moment, many scholars considered traditional rural sociology, which tended to focus on the community dynamics of rural life, to be inadequate for making sense of rapid changes occurring in the agriculture sector. In response, a new wave of scholars developed a more critically oriented perspective called “the new political economy of agriculture” (Friedland et al. 1991), which focused on the role of agriculture in capitalist development, the class location of family farmers, the rise of agribusiness, and the fate of family farmers in advanced capitalist economies. Scholars would later broaden this approach by adopting a food systems perspective, which incorporates patterns of food distribution and consumption into the analysis, and by applying it to an international, and eventually global, scale. In general terms, the political economy of agriculture and food perspective sees agri-food system dynamics emerging from the interplay of state structures and policy, markets, and the organized actions of social actors such as farmers, corporations, and consumers.

Just as no society can exist without meeting the food needs of most of its members, the agri-food sector has been central to the development and reproduction of capitalist societies. In capitalist societies, in which food is progressively commodified over time, the food question is largely a function of the purchasing power of social classes in relation to food prices. Likewise, in a capitalist economy, prices and markets play an important role in shaping agricultural production among commercial farmers. Agriculture has played a somewhat paradoxical role in capitalist development. On the one hand, capitalist development is associated with the declining importance of agriculture in relation to manufacturing and other economic sectors. On the other hand, the industrialization of agriculture and the rise of a capitalist food industry have made the agri-food sector into big business. Agriculture represents about 6% of global GDP, and worldwide food sales were estimated at \$US eight trillion in 2008 (Clapp 2012, p. 7). Today, agri-food

corporations have enormous influence over some food markets and have exerted considerable political influence as well.

State regulation of the food supply goes back centuries, with the British Assize of bread of the thirteenth century, which regulated bread price, weight, and quality, being an early example. In capitalist societies, states have used agriculture and food policy to regulate markets, often in response to the political pressure of class interests such as farmers, working-class consumers, or agribusiness. Farm policies have tended to address some of the distinctive features of agricultural markets: a very large number of sellers (farmers) compared to buyers (food processors), price volatility, the perishable nature of food commodities, the seasonal variability in supplies of some commodities, and the non-elasticity of food demand (i.e., the fact that, past a certain threshold, demand for food does not increase with rising income). Governments have used price supports and farm subsidies, for instance, to meet farm income and rural development objectives or state-mandated marketing bodies to even out the imbalance in market power between farmers and agribusiness. Governments have also regulated key aspects of the food supply, including food prices, safety, quality, and nutrition, with food security being one of the overriding objectives. Over the last few decades, the regulation of agri-food markets and food supplies has become increasingly internationalized with the emergence of institutions such as the United Nations’ Food and Agriculture Organization, the World Trade Organization (see below), and Codex Alimentarius, a regulatory body charged with establishing international food safety and quality standards.

The accelerating globalization of agri-food sectors has led scholars to recast the political economy framework in global terms. Broadly speaking, the global political economy of agriculture and food poses questions such as the following: How can persistent hunger in a world of plenty be explained? What is to be the fate of global farming classes, especially small peasant farmers in the global South and small and medium family farms in the global North? What role are

global corporations playing in the integration, harmonization, and commodification of food systems? How is the global food economy to be regulated? An emerging political economy of *food crisis* has begun to grapple with the recent, deep-seated convulsions of the global food economy, which include price spikes, rising hunger, the climate crisis, and ecological degradation (Magdoff and Tokar 2010). These issues are examined in more detail below. The next section traces the origins and evolution of the global food economy.

The Global Food Economy

Today's global food economy has its earliest roots in the wave of European colonialism that began in the fifteenth century. As part of the colonizing process, European powers appropriated indigenous land and labor for the production of food and fiber. Vast swaths of the colonized world were converted to plantation agriculture producing valuable commodities such as coffee, cotton, tea, sugar, rubber, and spices. This disrupted and disorganized the indigenous social systems, including food provisioning, and radically changed the ecology of the colonized places (Weis 2007). The colonial-era trade created an international division of labor in which colonized zones specialized in raw agricultural products and European states in manufacturing. Over the long term, this specialization created, in some parts of the global South, a dependence on a narrow range of agricultural commodities for export earnings.

A world market in food *staples* did not emerge until the latter half of the nineteenth century. This only occurred with the massive increase in the international wheat trade resulting from the opening of new farming frontiers in settler-states such as Canada, the USA, Australia, and Argentina. As part of a push for national development, settler-states dramatically expanded their production of wheat, beef, and other food staples for export. In turn, the industrializing states of Europe, led by the UK, turned increasingly to cheap imports of food staples to feed a burgeoning working class. This new international division of labor formed

the basis of the first capitalist “food regime” (Friedmann and McMichael 1989), a coordinated set of relations organizing food production, distribution, and consumption on a world scale. During the first food regime, the international food trade was organized mostly on the basis of free trade, a key part of the UK's strategy for economic and political dominance. In the settler-states, family farms, based on household labor and land ownership, became the dominant form of agricultural production, and farm households became an important political and economic class. The earliest agribusiness companies, consisting of grain trading firms, farm machinery manufacturers, and early food processing businesses, also emerged at this time.

The chaos of the two World Wars and the Great Depression disrupted and ultimately unraveled the first food regime as wartime food crises and the collapse of agricultural markets caused increasing conflicts among farmers, governments, and consumer classes.

Only with the stabilization of the international system and the world economy after World War II did a new food regime emerge. During the second food regime, states would play a much more direct role in regulating domestic food and farm sectors as well as the international agricultural trade. Governments of industrialized states introduced wide-ranging farm supports that sought to stabilize farm incomes and promoted the further industrialization of agriculture. These policies tended to create large, chronic surpluses of major food commodities, which in turn became a serious economic and political problem. Taking the lead from the USA, the dominant economic and political state of the era, governments dealt with surpluses by pushing their exports into new markets, often through food aid programs, and by encouraging the rapid development of intensive livestock and food processing industries. These industries, referred to by Friedmann (1994) as the “livestock complex” and the “durable foods complex,” transformed grain into meat and processed foods, both of which became hallmarks of postwar diets. Large multinational corporations consolidated their power over several aspects of the agri-food sector, including grain trading, food

processing, and farm chemicals, sometimes creating vertically and horizontally integrated conglomerates (e.g., Cargill and ADM).

Meanwhile, the end of World War II led to a rapid wave of decolonization in the global South. The newly independent states of the Third World pursued economic development based on a Western model of industrialization. As a result, many Third World states accepted food aid (cheap, but not free, shipments of grain from the USA and other states) as a basis for subsidizing working-class wages and stimulating industrialization. The second food regime therefore produced new international flows of food, with many parts of the Third World continuing to provide international markets with tropical commodities, but industrialized states increasing their exports of grain and meat products into the global South.

These patterns were fairly stable until the oil and food shocks of the early 1970s, which disrupted the global capitalist economy. In 1972–1973, food prices spiked, partly because of a massive sale of US grain to the USSR, which marked a reversal of the long-standing American trade embargo with the communist world. The end of this embargo temporarily erased grain surpluses, which led farmers in the industrialized world to expand production, at the urging of governments. However, by the late 1970s, a return to surpluses combined with the European Economic Community's entry into the world market as a major exporter in its own right caused increasing market volatility. As competition over market share intensified, the dominant exporters, the USA and the EU, expanded their export subsidies and other forms of agricultural support. This depressed world prices, causing hardship for industrialized farmers in countries such as Canada, Australia, and Argentina. Meanwhile, the conditions of the 1970s sowed the seeds of a crisis for many Third World states. Rising oil prices and a recession among the industrialized states caused the price of imports to rise just as export opportunities declined. Earnings from the export of tropical agricultural commodities plummeted as the terms of trade for Third World states worsened. Many of these borrowed heavily in order to keep up with development goals and to

finance imports. Higher grain prices during the mid-1970s caused wealthy countries to scale back their food aid programs, leaving former aid recipients dependent on imports of now commercially priced grains from the North. By the 1980s, rapidly rising interest rates, caused by the USA's tightening of the money supply, triggered a severe debt crisis for many Third World states. The turmoil of the 1970s and 1980s undermined many of the assumptions and practices that had stabilized the second food regime.

In the search for a solution to these problems, powerful states, led by the USA, and multilateral lending institutions adopted a neoliberal philosophy that called for freer trade and less government involvement in agriculture. On the one hand, freer trade was intended to curb the spiraling subsidy war among major exporters and to expand international trade opportunities. On the other hand, reducing government support for agriculture was meant to allow "market forces," including international competition, to allocate resources in the farming sector, even if this undermined the viability of family farming. In the global South, debt crises led many states to seek emergency bailouts from the International Monetary Fund and World Bank, who made the loans conditional on the adoption of "structural adjustment plans" inspired by neoliberal economics. Structural adjustment policies encouraged governments to increase agricultural exports, reduce import restrictions, and cut funding to rural development and farm support programs. These reforms reoriented the farming sectors of many countries – shifting away from self-sufficiency and towards agro-exports – and further integrated the global South into the global food economy. From the 1980s onwards, many countries scaled up their production of counterseasonal fresh fruits and vegetables, meat, seafood, and animal feed for the global market. This reorientation often came at the expense of smaller-scale peasant farmers, who found it increasingly impossible to compete with the flood of cheap imports from abroad.

The neoliberal restructuring of agriculture was institutionalized in the Agreement on Agriculture (AoA), a subagreement of the World Trade Organization, signed in 1995. This agreement sought

to liberalize agricultural trade by harmonizing food standards, reducing trade barriers, and tackling export subsidies. Wealthy agro-exporting countries, supported by an influential agribusiness lobby, sought better access to new markets in the global South as well as an end to the destructive USA–EU subsidy war. Meanwhile, many countries in the global South hoped that the AoA would level the playing field by reigning in rich-country subsidies and providing better access to markets in the global North. Far from resolving the imbalances of the global food system, however, the AoA has, according to its critics, accentuated and legitimized them (Pritchard 2009). For one, the USA and EU have made little progress in reducing their overall agricultural spending, to the frustration of competing agro-exporters. Furthermore, countries of the global South have been locked into a new trading regime that exposes them to the cheap exports of wealthy countries with little benefit in terms of improved market access. By the early 2000s, these issues became a stumbling block in the attempt to reach a new WTO deal, as a coalition of global South countries broke off the negotiations over the lack of progress on rich-country subsidies. The talks have been moribund since 2008, though the 1995 AoA provisions remain in effect.

In the neoliberal era, agri-food corporations have extended and consolidated their influence over the global food economy. In a process facilitated by the liberalization of agri-food sectors, agribusiness firms have established sprawling international empires able to source raw materials cheaply, exploit differential labor regimes, and target lucrative markets with an eye to maximizing profits. Agri-food companies have likewise developed increasing influence over the regulation of food quality, with private standards replacing or being superimposed upon weakened public standards (Friedmann 2005). These private standards may appeal to wealthy consumers as assurances that foods are “safe,” “green,” or “fair.” Poorer consumers, however, must make do with the standardized, highly processed, and sometimes risky food products of the global food system.

Although the neoliberal period has led to an unprecedented integration of the global food economy, it has also produced growing conflicts. On the one hand, different social actors, regions, and agri-food sectors are integrated unevenly into the system, creating different sets of winners and losers. On the other hand, the dominance of neoliberal philosophy has sparked a debate over the principles and values that should guide societies’ relationships to food and agriculture. Neoliberalism tends to value entrepreneurship, individual liberty, and economic efficiency over solidarity, cooperation, and social justice. Applied to agriculture and food sectors, these values have translated into a sense that neoliberal reforms are a painful but necessary process for achieving a greater long-term good, the efficient allocation of resources. Critics of neoliberal philosophy contend that the most efficient allocation of resources is not necessarily, or even most often, the most just and that markets, trade, and other economic processes should serve society, not the other way around.

These conflicting realities and worldviews have led to a series of instabilities and contradictions in the global food economy.

Crisis and Contradiction in the Global Food Economy

The food crisis of 2007–2008 shone a spotlight on the weaknesses of the global food economy. Many agri-food scholars point out, however, that the contradictions of the system run deeper, since many present-day crises are the expression of long-running tendencies. Perhaps the most visible failing of the global food system is persistent – indeed, worsening – hunger and malnutrition. In the wake of the food crisis, the FAO estimated that over one billion people went hungry in 2009, an increase of approximately 150 million from preceding years. Yet, even before the price spikes, rates of undernourishment remained stubbornly high, particularly for sub-Saharan Africa and South Asia. With rapid price increases such as those in 2007–2008 and 2011, vulnerable households are pushed over the edge into food

insecurity. The causes behind recent food crises include both latent problems, such as the decades-long marginalization of small-scale farmers and rural people, who are the most vulnerable to hunger, and more recent phenomena, such as the biofuels boom, which shifts resources away from food production, rising global demand for meat, failed crops, a weakening US dollar, and growing financial speculation in food commodities. While food crisis conditions have led to increasing investment in agriculture, which many have welcomed, some new forms of investment have been highly controversial. Wealthy governments, sovereign wealth funds, and private investors have, since the mid-2000s, begun to acquire large swaths of productive farmland in developing countries, especially Africa, in what some have called a “global land grab.” The concern is that these outside investors will, in pursuing their own ends, dispossess and disenfranchise vulnerable smallholders. Another controversial trend is increasing food system financialization (Clapp 2012), the process whereby financial interests have come to exert increasing influence over agri-food markets and prices through speculative investment. Here the concern is that speculation could exacerbate food price volatility at the expense of poor, food-insecure households.

At the other end of the spectrum, industrialized states and, to an increasing extent, middle income and developing countries are facing growing rates of diabetes, obesity, and heart diseases. While the causes of these diseases are complex, the overconsumption of some foods, particularly meat, highly processed foods, and fast foods, is a major contributor. Diet-related diseases such as these pose a significant public health problem and place a strain on health-care resources. Yet, addressing the problem is difficult given that food choices are made in a food environment saturated with advertisements for foods high in fat and empty calories. This global juxtaposition of the “stuffed and starved” is a symptom of a food system that is gravely out of balance (Patel 2007).

The plight of the world’s farmers is another of the global food economy’s most pressing crises. In the global North, three decades of neoliberal reforms have accelerated the decline of small- and

medium-sized family farms. The remaining farms are highly productive, highly capitalized, and very large, yet many farm operations cannot survive without substantial support from off-farm income and/or government programs. Likewise, these farms are increasingly likely to be integrated into corporate food chains through contracting arrangements wherein farmers have only limited negotiating power. In the global South, chronic underspending on rural development and agriculture, the corrosive effect of cheap imports, the overreliance on some export commodities, and the dominance of corporate agro-exports have left smallholder farmers in ever more precarious conditions. Indeed, tens of millions of small farmers have, in recent decades, abandoned the countryside for the city, contributing to the “planet of slums” phenomenon (Davis 2006). Even if cities offer better opportunities for some, the scale and speed at which this rural–urban migration is occurring mean that many migrants become a part of the “surplus population” for which there are no (or only poor) jobs, insecure housing, and few if any basic amenities. Those small-scale farmers that stay on the land have shown great resilience but continue to face hunger – many poor households are still net buyers of food – poor access to markets, low productivity, and worsening environmental conditions.

The ecological cost of industrial food production is another highly contentious issue. As Weis (2010) has argued, the productivity of the industrial food system is underwritten by a series of “biophysical overrides” that boost yields but externalize environmental costs. The common denominator for each of these overrides – artificial fertilizers, chemical pesticides, and cheap fuel for machinery – is fossil fuels. The ecological harm wrought by the extraction and burning of fossil fuels is unaccounted for in the cheap price of fuel and other petroleum inputs, which masks the true cost of industrial food. In addition, a highly integrated global food economy depends on cheap fuel to transport food from farm to plate, often across thousands of miles. The global agri-food sector is therefore a major contributor to greenhouse gas emissions and climate instability. This

is ironic since the agricultural sector stands to be among the most negatively affected by climate shocks such as drought, flood, and extreme heat. The spread of industrial agriculture is also associated with biodiversity loss, the toxic effects of pesticides on nontarget species, and damage to waterways from the overaccumulation of artificial nutrients.

Finally, the spread of industrial livestock operations and meat-centered diets raises animal welfare and social justice issues in the global food system. Weis (2007) has documented the rapid rise of the global livestock sector, citing an estimated fivefold increase in global meat production from 1950 to the early 2000s. The global farm animal population puts a huge strain on resources – referred to as the “ecological hoofprint” – including land, water, and waste-absorption capacity. Given the inefficient rate at which grain and water are converted into food nutrients in meat, the rising global appetite for meat tends only to exacerbate the inequalities between the world’s poorest and more affluent consumers. Moreover, industrial methods tend to maximize animal turnover through speedup and other technologies, exacting a heavy toll on animal well-being.

Countermovements and Alternatives

A wide range of social actors, including farmers, NGOs, academics, food system activists, and environmentalists, working within and across their various networks, have challenged the dominant relations of the global food system. Three broad sets of alternative approaches, each grounded in an ethical critique of the status quo, are highlighted here. First, social actors have created alternative food networks (AFNs) that circumvent the regular channels of production, distribution, and consumption of the global food system. At local and regional scales, AFNs include farmers’ markets and community-supported agriculture schemes, where consumers invest in a local farm in order to share in the risks and rewards of food production. These types of AFNs reconnect farmer and consumer and return

a larger share of the food dollar to farmers. At an international scale, fair trade schemes for commodities such as coffee, tea, sugar, chocolate, and flowers provide a guaranteed price to small-holder farmers, ensure decent labor conditions, and often include environmental provisions. By purchasing fair trade-certified products, consumers engage in a form of ethical consumption where social and ecological values are added to other considerations such as price and quality.

Second, recent food crises have led to a call among some multilateral bodies, NGOs, activists, and academics for a new commitment to farmer-led rural development. The idea here is that investing in the livelihoods of poor farmers is the best way to tackle the food, farming, and climate crises. Since hunger and poverty disproportionately affect farmers and rural populations, raising the incomes of small-scale farmers must be a priority. This can best be achieved, according to this view, by providing farmers with the knowledge and tools to make the best possible use of their existing resources, including land, water, and agro-biodiversity. Indeed, low-input, resource-conserving methods – referred to as agroecology – have been shown to significantly raise yields and, by extension, the incomes and food security of poor households. The International Assessment of Agricultural Knowledge, Science and Technology for Development (IAASTD), a major UN-sponsored study, favored pro-poor, agroecological strategies over continued agro-industrialization as a means of meeting the challenges of global food security, poverty alleviation, and climate stabilization.

Third, social movements of various stripes have rallied behind food sovereignty, a far-reaching vision for putting human rights at the center of the food system. The idea of food sovereignty was first articulated by Via Campesina, an international peasants’ movement. Above all, food sovereignty asserts the right of peoples to democratic control over food and farming. In practice, food sovereignty requires that agri-food systems provide a decent living for farmers, ensure that the food needs of all members of the society are met, and create the conditions for long-term sustainability. The food sovereignty movement sees the neoliberal framework of

liberalization, commodification, and corporate dominance as illegitimate and seeks to replace it with decentralized, democratically governed food systems. Food sovereignty is in large measure compatible with the other alternatives outlined above but goes beyond them by proposing a paradigmatic change that integrates ecological, social, and political goals.

Summary

Over 150 years of global capitalist development, an increasingly integrated global food system has tied distant producers, consumers, and ecosystems into new relations. The consolidation of the corporate-dominated global food system since the 1980s has led to a series of ruptures, dislocations, and conflicts that have raised pressing social, ecological, and political questions. The trajectory of the global food system will be influenced by the competing interests and strategies of dominant social actors, including states and agri-food corporations committed to the status quo, and coalitions of civil society challengers committed to deep-seated change.

Rural, Urban, and Wild

Aristotle said that humans are by nature “political animals” (Greek *polis*, town, Aristotle, *Politics*, 1, 2). We live in towns; we are civilized. But by nature too, we are residents on landscapes, placed in a more comprehensive community of life and life support. The rural environment is more central, more basic than the urban or wild environments. Humans may believe they have a right to a healthy and productive environment, providing needed commodities – soil, food, water, timber, and natural resources. Still, an encounter with all three dimensions – urban, rural, and wild – protects a comprehensive experience of human identity. Nature is *resources*, but in a deeper perspective, nature is the *source* that produces life, the ecosystemic life-support system.

Culture remains tethered to the biosystem. Culture depends on airflow, water cycles, sunshine, nitrogen fixation, decomposition bacteria, fungi, the ozone layer, food chains, insect pollination, soils, earthworms, climates, oceans, and genetic materials. An ecology still lies in the background of culture. In any future that we can presently envision, some sort of comprehensive or inclusive environmental fitness is required. Nature is not gone. Nor are we post-natural; rather, nature is forever lingering around. Humans and this planet have entwined destinies.

Such more comprehensive fitness is more than just a reliable supply of wheat from the breadbasket plains. People have a sense of place. Americans sing, with goose bumps, of “mountain majesties above fruited plains.” All peoples need a sense of “my country,” of their social communities in place on a sustaining landscape they possess in care and in love. The English love their countrysides. The promised land has been central in Hebrew faith. Both involve a rural land tended

with care and, more inclusively, an embodied sense of residence on a landscape.

Caring for landscapes goes back to Adam and Eve, to baseline human agricultural experience. The first couple was set in Eden “to till it and keep it” (Genesis 2.15). “Be fruitful and multiply, and fill the earth and subdue it; and have dominion . . .” (Genesis 1.27–28). Even hunter-gatherers attempted some landscape tending, such as setting wildfires to increase grass and attract game. With the coming of agriculture, humans found tilling the good earth a toilsome blessing, reflected in the Genesis fall: “In the sweat of your face you shall eat bread” (Genesis 3.19). In the struggle for food and health, we want a naturally healthy body, but we do not want naturally healthy wild ecosystems and nothing more. We transform them agriculturally; we are stewards who garden the Earth. We “produce” food and fiber. Still, some dimensions of health pervade both wild and agricultural nature – the need for air, water, fertile and nontoxic soil, sunshine, suitable climate, and a land with promise that can be tended as a promised land.

This ancient pursuit continues. How ought humans to reside on landscapes on which they must earn a living? Some prominent figures in thinking philosophically and ecologically about agriculture are as follows: Paul Thompson (Thompson 1995, 2010); Wes Jackson, founder and president of The Land Institute in Salina, Kansas (Jackson 1994, 2010); Fred Kirschenmann, North Dakota organic farmer and also at the Leopold Center for Sustainable Development, Iowa State University (Kirschenmann 2010); and Wendell Berry (2002).

Ecosystem Services

Natural systems have provided the wider envelope in which human agriculture (and culture) functions. “Ecosystem agriculturalists will take advantage of huge chunks of what works . . . the natural integrities of ecosystems worked out over the millennia” (Jackson 1985, p. 145). This surrounding milieu provides what are now called “ecosystem services,” contributions of natural

processes without which no agriculture (or culture) can flourish, but which do not classically enter into the accounting of economists. These include primary photosynthetic productivity, nutrient dispersal and cycling, pollination, food, fuel, cleansing air and water, soil renewal, and living space that is habitable and pleasant. Wild pollinators, for example, provide free pollination; in some areas honeybee colonies must be supplied to replace lost wild pollinators, at a cost of billions of dollars. Analysts who examine this may call their discipline ecological economics and distinguish it from environmental economics, which is classical economics applied to natural systems thought of as market resources. Ecological economists are holists who think more ecologically than environmental economists.

Robert Costanza led an effort to value such ecosystem services. He came up with a value of about \$33 trillion, in a range of \$16 trillion to \$54 trillion (Costanza et al. 1997; Pimm 1997). The global GDP in 1997, the year of the study, was \$27 trillion. So natural ecosystem services may exceed the entire output of the global human economy. As might be expected, the study was criticized, although critics agreed that “externalities” (as classical economists call them) – benefits from Mother Nature that belong to no one in particular and so are enjoyed for free by all – are huge. These common benefits do indeed force us to rethink what we ought to do in terms of our treatment of nature. This may also be called “translational ecology.”

Ecological economists find that this goal of forever giving people more and more, however humane, drives an escalating degradation of the natural environment, undermines ecosystem services, makes it harder to grow enough food for people, reduces biodiversity, and makes the rich richer and the poor poorer. Such a humane economy is inseparably entwined with biological processes, a bioeconomics (Costanza et al. 1997; Spash 1999; Kolstad 2000; Daly and Farley 2004; Common and Stagl 2005; Millennium Ecosystem Assessment 2005).

Ecological economics thinks of the flow of energy and materials that enter and exit the economy as a kind of metabolism, digesting life

nutrients, but needing environmental sources and sinks, analogous to organisms in their environment. They may worry about pushing crop yields and losing the natural fertility of the soil and replacing this with synthetic agricultural fertilizers in increasing amounts, even if this increases yields in the short term. Or they may worry about what high pesticide use is doing to the rivers and groundwater. Carrying capacity ought to govern resource use, rather than maximum exploitation. Environmental integrity and quality is as central as are production, growth, and profit.

A massive *Millennium Ecosystem Assessment*, sponsored by the United Nations, involving over 1300 experts from almost 100 nations, begins: “At the heart of this assessment is a stark warning. Human activity is putting such strain on the natural functions of Earth that the ability of the planet’s ecosystems to sustain future generations can no longer be taken for granted” (Millennium Ecosystem Assessment 2005, p. 5). The principal authors conclude:

We lack a robust theoretical basis for linking ecological diversity to ecosystem dynamics and, in turn, to ecosystem services underlying human well-being. . . . The most catastrophic changes in ecosystem services identified in the MA (*Millennium Assessment*) involved nonlinear or abrupt shifts. We lack the ability to predict thresholds for such changes, whether or not such a change may be reversible, and how individuals and societies will respond. . . . Relations between ecosystem services and human well-being are poorly understood. (Carpenter et al. 2006).

In a review of biodiversity in ecosystem functioning, the authors conclude: “Maintaining a high proportion of biological diversity leads to efficient and stable levels of ecosystem functioning. . . . Protecting biodiversity is a goal of fundamental importance and can support efforts to safeguard the intrinsic capacity of ecosystems for self-renewal, adaptive dynamics, and supporting humanity now and for generations to come” (Naeem et al. 2012, pp. 1405–1406).

Some critics reply that, moving into the Anthropocene epoch, humans are creating novel ecosystems, new combinations of species under new biotic and abiotic conditions. More than 80% of all people live in densely populated rural,

village, and urban landscapes, what may be called “anthropogenic biomes” (Ellis and Ramankutty 2008). These critics further argue that adaptive ecosystem management approaches must explicitly acknowledge the current status and predict the future conditions of these systems. Old styles of management, which focused on removing undesirable species or conditions from ecosystems to return them to a prior condition, are no longer sufficient. We need to consider, and experiment with, novel outcomes or trajectories, rather than simply take preventative or therapeutic measures (Seastedt et al. 2008).

But ecological economists are doubtful about all this scaled-up, clever management of rural and wild lands. We have too much experience already with unexpected outcomes (e.g., kudzu, CO₂ in the atmosphere). Maybe even in the Anthropocene, we need to keep (as Wes Jackson says) “huge chunks” of what has worked well for millennia.

Farming, Food, Human, and Ecological Health

People work to domesticate their landscapes. They have grazed and plowed fields, cleared forests, planted crops, domesticated animals, and built roads, canals, and dams. Imperial China built irrigation canals and deforested mountains. The great Southeast Asian rivers were lined with rice paddies, and their well-watered deltas have proved superb locations for the cultivation of wet rice, the staple food of much of the population. Nepalis terraced their hillsides for more, drier rice. The Hebrews, in Biblical times, terraced theirs to grow wheat. Americans had their manifest destiny to conquer their continent, planting where they could and making the rest range for their cattle. Their wheat is not native to their landscape; in fact Americans eat almost nothing that was native to North America. Soviet socialism pressed a vast plan to reinvent nature, transforming it into the obedient servant of human society. People try to get the most they can out of their agriculture.

“Domesticated nature in its simplest form means nature exploited and controlled” (Kareiva et al. 2007). Humans reshape their environments,

rather than being themselves morphologically and genetically reshaped to fit their changing environments. So entering an Anthropocene epoch is just continuing what we have always been doing.

Yes, but the recent century has dramatically escalated the classical transformations. Human-dominated ecosystems now cover more of Earth’s land surface than do wild ecosystems (Foley et al. 2005). Nature now bears the marks of human influence more widely than ever before. Humans now consume 30–40% of all terrestrial net primary production (Vitousek et al. 1986; Imhoff et al. 2004). Humans produce more reactive nitrogen than all other terrestrial processes combined (Galloway 2004). Human agriculture, construction, and mining move more earth than do the natural processes of rock uplift and erosion (Wilkinson and McElroy 2007). These human activities alter the composition of the atmosphere, the soil, levels of biodiversity, and energy flows within food webs enough to threaten important ecosystem services. Most of life for most people takes place on landscapes that are a hybrid tapestry of nature and culture and rural, agricultural, pastoral landscapes. Humans have a huge “ecological footprint.”

According to a widely held account (descending from the philosopher John Locke), value arises when nature is mixed with human “labor” or “industry,” with the human labor adding most of the value. A person finds little food or shelter hiking through a forest; a farmer cuts down the trees, builds a house with the wood, and plants a vegetable garden, which must be tended or else there will be mostly weeds. Where a natural “source” can be “redirected” into channels of human interest and preference, nature is redone, “resourced,” and made over into an artifact that we can use. Nature is “transformed” into a more desirable humanized form. If you prefer a biological word, human values and natural values are “symbiotic.” If nature means absolutely pristine nature, totally unaffected by human activities, past or present, there is relatively little remaining on Earth. If culture means totally denatured, reconstructed, and civilized with no dependence on natural systems, there is none of that on Earth either. What is all over the landscapes is nature linked with human identity.

So are we to celebrate this escalation of human agricultural powers? Or should we be concerned about it? Have we passed our landscape-carrying capacity? Fewer farmers feed more people. In the United States in 1850, less than 20% of Americans lived in towns and cities. Today more than 80% are urban, and the prosperity in cities is made possible by increasingly productive mechanized agriculture on the farms, as we next see. This urbanization has also decoupled increasing numbers of humans from any direct experience of agriculture. A typical reply will be that all this is a good thing, provided only that the agriculture is sustainable, provides the population with healthy food, and continues on healthy ecosystems. One way to keep people in touch with their ecosystems is to eat local and eat organic food.

Ecosystem *health* is a somewhat metaphorical term, extrapolated from health as found in individual organisms, but it is a term to which people relate easily. Everybody wants to be healthy and to live in healthy places. “An ecological system is healthy and free from ‘distress syndrome’ if it is stable and sustainable – that is, if it is active and maintains its organization and autonomy over time and is resilient to stress” (Costanza et al. 1992, p. 9; Mistretta 2002). Biological *integrity* has as a baseline index the ecosystem that was originally there before human changes, the natural history, while biological *health* may – but need not always – require all the species that were originally there. There may be culturally introduced replacements. If there is health, these replacements will thereafter function with minimal management intervention. Generally, environmentalists dislike moving to a bioengineered agriculture that involves a constantly doctored landscape (removing toxics from streams, bringing in bees to fertilize the crops).

The 1998–1999 Malaysian Nipah virus epidemic emerged when pigs (raised for international trade) were crammed together in pens located in or near orchards. The orchards attracted fruit bats whose normal habitats had been disrupted by deforestation; their droppings contained the as yet unknown paramyxovirus and infected the pigs. The overcrowding led to explosive transmission rates and to infections in pig handlers. So a

virus that was once not disruptively epidemic became so because of human disruptions of natural habitats of bats and overcrowding of pigs, driven by global commercial interests. The Malaysian government culled over one million pigs (Morens et al. 2004; Dobson 2005). Globalism sets up atypical ecological conditions favorable for invasives and pathogens. The result is human disease but the inclusive framework is agricultural and social upset of natural ecologies.

One of the classical proverbs of ecologists is that everything is connected to everything else. This proverb is proving true with links between ecological and human health, links that tie local to global events, in wild nature, agriculture, and culture. The larger framework requires thinking holistically “based on the understanding that there is only one world – and only one health” (Karesh and Cook 2005, p. 50; Rolston 2005). “Health effects ripple throughout the web of life. Health connects all species” (Tabor 2002, p. 9). Human health requires thinking in ecological contexts, increasingly in more global ones.

Industrial Agriculture

Yes, classically ecosystems did provide the wider envelope in which human systems of agriculture have functioned. But in the Anthropocene age, we have moved past that. Now and henceforth, the principal way to think of agricultural lands is as capital. Economists may speak of “capitalizing nature.” Land and resources are “natural capital.” We have “factory” or “corporate” farming. Farmers ought to be “industrious.” Traditional agriculture was powered by muscle and blood, humans and horses, and perhaps some water power for irrigation or grinding grains. Commercial agriculture is powered by engines and gears, tractors, combines, and harvesters, in turn powered by fossil energy. Farming is technoscientific, with innovations in agricultural machinery, massive irrigation dams, and genetic technology, producing high-yield varieties, large-scale production, huge fields, massive harvests, patent protection, and global trade. Land is part of the machinery. There are confined animal

operations (CAFOs); animals are fed enriched food, growth hormones, and antibiotics to assure maximum productivity in terms of size, taste, and sales. Traditional fertilizer was manure; now the increase comes from synthetic nitrogen and other fertilizers.

There are positive results for those in developed countries: cheaper and more plentiful food in nearby supermarkets and myriads of workers employed in the distribution system, from growers to harvesters to processors to sellers. Those in developing countries are better fed (at least they can be; many are obese). Agricultural production is over ten times what it was a century back, although the number of farmers has dropped dramatically. Now, we can support escalating populations with escalating appetites in consumption. In the 1930s, 24% of the American population worked in agriculture compared to 1.5% in 2002; in 1940, each farm worker supplied 11 consumers, whereas in 2002, each worker supplied 90 consumers (Scully 2002, p. 29). The hope is to transfer such productivity to developing nations and feed the starving world, a “Green Revolution.”

But there is bad with the good. Often there are serious environmental and social costs (Gardner 2002). There is global warming from heavy use of fossil fuels. The large scale of disturbed soil for planting monocultures invites invasives, weedy plants, and exotic insects, microbes, and fungi, which must be controlled. There are increased health risks from pesticides and other agricultural chemicals, both to wildlife and to humans. Many agriculturally used chemicals have long lifetimes; they spill over and migrate from the sites where they are applied; they build up in food chains. We woke up to this with discoveries about the unintended consequences of the pesticide DDT, Rachel Carson’s “Silent Spring.” In places, human breast milk has become contaminated at levels that exceed those permitted in dairy milk sold in stores. Many pesticides seem to be endocrine disrupters, disturbing reproduction. Pollution that leaks into groundwater is often impossible to remove. Pollution released into the air moves around the globe. One problem here is that agricultural uses (in contrast with industrial

plants) are nonpoint sources. It is hard for regulators to pinpoint who is responsible exactly when, where, and how much. Nitrogen in fertilizer on farms in the Midwest has been traced to fish kills in the Gulf of Mexico.

The victims who live downwater or downwind never gave any free, informed consent and usually have no means of proving their damages or asserting their rights. The ill-health effects of pollution often show up first in women, especially pregnant women, and in children. The ill effects may never show up in most of the population, only in a segment of the population that is more susceptible (perhaps the senior citizens). With the long-lived pollutants, the benefits (agribusiness profits, cheap food) may be enjoyed at present, but the suffering (toxic groundwater carcinogens) is borne by future generations. The toxic effects of many of these pollutants can be much longer-lived than the human institutions set up to deal with them.

Longstanding public policies governing chemical design, production, and use need deep restructuring in the light of new science on the health and environmental effects of anthropogenic chemicals. The prevailing view is that we have to maximize yields, at risk of degrading ecosystems. Better to think more holistically. More organic farming can produce enough, healthier foods; it can even outperform chemically dependent farms in periods of drought and climatic stress (Seaman 2011). Such reforms are essential to safeguard ecosystem integrity, human health, and economic sustainability. The U.S. Congress has passed numerous laws to address these issues – notably the 1976 Toxic Substances Control Act, the 1977 Clean Water Act, the 1977 Clean Air Act, and the 1980 Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA, with its Superfund). But these issues escalate when one moves from the traditional family farm to industrial agriculture. Corporate agriculture, with its focus on increased production, sales, and profits, is not inclined to consider the externalities, the wider and long-term consequences of its operations. The family farm could still be contained in an ecosystemic envelope; industrial farming pushes that envelope toward ecosystemic collapse.

Agriculture in Developing Nations

The Millennium Ecosystem Assessment found that “the poor are most dependent on ecosystem services and vulnerable to their degradation” (Carpenter et al. 2006). In Nepal, one of the poorest nations on Earth, there are melting glaciers in the Himalayas, resulting in glacial lake outburst floods, destroying homes and crops. At the same time monsoon rainfall is increasingly erratic, often delayed past the season for planting rice, and producing landslides that destroy agricultural terraces. This is widely ascribed to global warming, the effects felt in a nation that contributes virtually nothing to CO₂ emissions. So far as this is true, the industrial nations are depriving poorer nations of their ecosystem services, vital to their agriculture.

The “Green Revolution” produced some positive results but came nowhere near solving the problem of feeding the world, and it is increasingly harder to bolster crop yields. Corporate agriculture, especially when faced with overproduction in developed countries, has turned to developing nations. But productivity improvements are hard to transmit there (Wilkinson 2009). This can be deliberate; high-yield varieties may be engineered so that farmers must purchase new seed each year. It can be more social or political. Often there are patent disputes or water relocations. Developing states may enter into agreements with large food corporations to grow food and may displace local farmers. There is often dispute over regulation and local corruption. Corporations may seek control over large amounts of land (“land grabbing”).

Foreign businesses entering local agricultural systems can upset them as often as improve them, since they are there to make a profit, perhaps to grow crops for export (palm oil, coffee, tea, soy, shrimp). Many agricultural systems may have worked for centuries, but with recent population explosions and resulting land degradation, those in developing nations increasingly need fertilizers to boost yields – synthetic fertilizers if they can get them – but such fertilizer will be proportionately much more expensive in developing nations. African soils are often not especially fertile, and

farmers there must pay two to four times the average world price for fertilizers (FAO 2008): prices are not competitive; fertilizer traders charge what they can get; and transportation is inefficient and expensive (sometimes carried on the backs of donkeys or women).

Industrial agriculture, critics often say, needs to be replaced by sustainable agriculture, and again, there are opportunities and challenges.

Sustainability: Local and Global

One powerful movement has been the turn to sustainable development, growing out of the United Nations Conference on Environment and Development in 1992. But there are two ways of thinking about sustainability. First, the economy can be prioritized: this is the usual case. Anything can be done to the environment, so long as the continuing development of the economy is not jeopardized. If economics is the driver, we will seek maximum harvests, a bioindustrial model, pushing for bigger and more efficient agriculture, so long as this is sustainable. What we must push for, according to the Royal Society of London, the world’s oldest scientific society, is “sustainable intensification” of reaping the benefits of exploiting the Earth (Royal Society 2009).

In a second way of thinking, the environment is prioritized. A “sustainable biosphere” model demands a baseline quality of environment. The economy must be worked out within such a policy for environmental quality objectives (clean air, water, stable agricultural soils, attractive residential landscapes, forests, mountains, rivers, rural lands, parks, wildlands, wildlife, renewable resources). Ecosystem services have to be sustained. The economy must be kept within an environmental orbit. One ought to conserve the ground matrix of life. Development is desired, but even more, society must learn to live within the carrying capacity of its landscapes. The model is land as community.

The Ecological Society of America advocates research and policy that will result in a “sustainable biosphere.” “Achieving a sustainable biosphere is the single most important task facing humankind today” (Risser et al. 1991). Any

sustainable economic development ethic needs to be brought under a sustainable ecosystems ethic. Development concerns need to focus on natural support systems as much as they do people's needs. "Sustainable" is an economic but also an environmental term. The fundamental flaw in "sustainable development" is that it typically sees the Earth only as resource.

Philosophers may enter the dialogue to claim that sustainability of any kind needs also to be fair and just. There is nothing in either ecology or economics per se that gives either any authority or skills at making these further social decisions. Perhaps ecologists can at least make the claim that any fair and just society, over time, requires a local, regional, and planetary sustainability. The ultimate unit of moral concern is the ultimate unit of survival, and that is the biosphere on this wonderland Earth.

Summary

Food and agriculture when linked together with ecosystems raise ethical issues, in addition to technological and scientific concerns. This requires considering rural, urban, and wild landscapes; ecosystem services; human and ecological health; industrial agriculture; agriculture in developing nations; and local and global sustainability.

Ecological utopia; Environmental utopia; Ideal ecological state

Introduction

Ecotopia, a novel written 1975 by Ernest Callenbach (1929–2012), describes an ideal ecologically oriented sustainable society (an ecological eutopia). The book discusses a wide variety of environmental topics of ethical relevance, including issues pertaining to organic food, healthy eating, organic agriculture, and sustainable forestry. The novel illustrates how these issues can be addressed ideally and practically. Sometimes the term ecotopia is also used loosely to refer to real existing ecological communities or blueprints of such communities. This entry, however, is focusing on the novel *Ecotopia* and its description of an ideal ecological state by the same name. The entry briefly situates the novel as a utopian text that is relevant in the context of the discourse on ecologically ideal living, and then it deals with two philosophical presuppositions of the fictitious state “Ecotopia,” sustainability and holistic well-being, before focusing on agricultural and food issues, respectively.

The novel *Ecotopia* is not a negative utopia (Dystopia) such as the dystopias *Brave New World* by Aldous Huxley (1932) and *Nineteen Eighty-Four* by George Orwell (1948). On the one hand, the utopian connotation of Callenbach's novel title, *Ecotopia*, points to a place (Greek: topos) that does not (Greek negation: “u-”) exist (yet) but also to a place which is good (Greek: “eu”). Hence, in many ways *Ecotopia* is an “eutopia” as, for example, Aldous Huxley's *Island* (1962). Some ecological paradigms of the fictitious state “Ecotopia” can be traced back to ancient Greek philosophy. Plato's dialogue *Nomoi* (2008) implies an ideal sustainable and stable state in terms of politics, society, population, households, and environment, while the Ancient Stoic philosophy valued the ideal of living according to (or in harmony with) nature.

The detailed and practical ecological solutions in *Ecotopia* include, but are not limited to, all possible types of waste management encompassing recycling programs, plant-derived biodegradable durable plastics, renewable energy, car and airplane free transportation, a wide variety of public transport opportunities (high and simple tech, such as

free public bicycles), organic farming, renaturation, and reforestation. In Ecotopia ecologically compatible high technology exists besides postmaterial(istic) lifestyles and attitudes of its citizens. Environmental paradigms of ethical relevance include a holistic concept of well-being, intra- and intergenerational justice, sustainability, steady-state economy, prices of goods that reflect the real costs (speak the “ecological truth”), anti-consumerism, slowly declining population, and strict environmental laws. The ecocentric worldview, with a romantic undertone regarding “mother” nature, gives preference to the quality of life and holistic well-being, but not to the economic paradigm of growth (Meinhold 2011).

Ethical-Philosophical Presuppositions

Ecocentric Worldview

Two pertinent ethical-philosophical presuppositions which guide both food production and food consumption in Ecotopia are based on an ecocentric worldview in general and more specifically a holistic and sustainable perspective on well-being in particular. In accordance with Ecological Economics’ or Deep Ecology’s view of the world, in Ecotopia humans and their economies are taken as subentities or subsystems of the ecosystem (mother nature). This argument is ontologically and logically consistent, since human economies take place within the context of ecological systems. The ecosystem is a *conditio sine qua non* for human economies, but the economy cannot exist sustainably without the sustainable support of the ecosystem (e.g., the sustainable supply of natural resources). Critics have referred to such ecocentric perspectives as ecofascism, especially if the ecosystem is always and without exception taking precedence over any other subentity or subsystem (cf. Callicott 2005). Ecotopians utilize natural resources by at the same time minimizing its impact on nature. But Ecotopians’ hunting and eating game, for example, is an indication that the ecosystem in Ecotopia is not always and not without exception taking precedence over human wants and needs.

Holistic Well-Being and Sustainability

In a time of accelerating and intensifying globalization, depletion of nonrenewable natural resources and growing disparity of incomes standard economics’ paradigm of growth are even more subject to critical scrutiny. Most economists concerned with sustainability and well-being accept that sustainability of nature, society, and economy is not achievable via economic growth alone. Callenbach’s Ecotopia developed a contrasting worldview in which economy’s, society’s, and nature’s sustainability is a consequence of a “steady-state” economy in which economic growth is not an important indicator for measuring economic progress or society’s well-being (Thailand’s King Bhumibol Adulyadej proposed a similar concept of sustainability, the Philosophy of Sufficiency Economy, in which economic growth plays a less important part, while the Buddhist value of moderation is considered a key for the improvement of general well-being).

In Ecotopia the quality of life or holistic well-being of humans and the ecosystem is considered key indicators of a philosophy of a good life in general and a sound economy in particular. This paradigm of holistic well-being is similar to since 1972 ongoing attempts in Bhutan which established gross national happiness (GNH), instead of gross national product (GNP), as major indicator of a society’s well-being.

Low Consumption and Justice

This relativization of economic-monetary values and the accentuation of holistic well-being are also manifested in prices of goods and services that reflect the real costs. An ethically just price for goods and services includes, for example, costs that reflect and thus monetarize environmental and health impacts. The price of fabric, for example, is comparatively expensive due to its high production costs, which “internalize” (monetarize) health and environmental implications (e.g., external effects such as air, water, or soil pollution). Another indication of the relativization of economic-monetary values is an anti-consumerist attitude, which manifests for example in low consumption lifestyles and in the

popularity of easily maintainable and repairable products that have a long lifespan.

Well-being in Ecotopia is considered to be of importance for all currently living humans (intragenerational or intragenerational justice) but beyond that also for future generations (intergenerational or intergenerational justice). The latter is manifested in Ecotopians concern for nonrenewable and renewable resources (e.g., the sustainable forestry and the narrowly regulated and closely monitored harvesting of timber, which has been the paragon for sustainability ever since).

Agriculture

Ecotopian farming regulations permit neither non-organic fertilizers nor herbicides/insecticides. Fields and forests planted in organic, sustainable, polyculture supply natural, plant-derived renewable, raw materials for building, clothes, and other goods. Organic and sustainable farming also includes waste recycling that is not only practiced on farms but in all sectors. Farms as well as corporations are co-owned in such a way that all workers are at the same time owners of the business. Forestry regulations based on intergenerational justice demand personal commitment of potential buyers of large amounts of timber who have to work in the forest (e.g., planting new trees) for a certain time that is equivalent to the amount of wood they want to purchase, thereby promoting awareness for sustainability. Prices of all goods, raw materials, and energy reflect the real costs or the ecological footprint. Technically this means that ecological costs (externalities) are monetarized (internalized). This is the reason why prices of fabrics such as cotton and wool are comparably high whereas synthetics are not permitted. Leather and fur are preferred raw materials for clothes and bags instead of fabrics, because of their durability (sustainability) and due to their natural origin. Leather, fur, and fabrics are frequently reused and recycled. Environmental pollution is strictly enforced and punished with severe jail sentences. Farming and production, including energy

production, are decentralized. Education fosters environmental awareness by theoretical lessons in biology, environmental philosophy, excursions, and practical garden work.

Food

In Callenbach's ideal ecological state, the ethics of food and its consumption reflect the conception of an antithesis to today's still prevalent American mainstream diet which is seen as ethically inappropriate due to its health risks and because of its environmental externalities. Ecotopian food is (technically) organic, healthy, less processed, and without refined sugar. Besides organic fruit and vegetables from farms and gardens, so-called "core stores" supply healthy but cheaply produced food items such as dried, frozen, and otherwise preserved food, for example, bread, beans, rice, and other staples. If packed, the packaging is biodegradable and recyclable or consists of standardized reusable containers all of which eliminate or at least minimize external effects on environment and consumers. The food ethical antithesis to mainstream nutrition in western and western-oriented cultures consists also in partially environmental law backup bans on items such as convenience food, sodas, sweetened foods, chewing gum, and microwave ovens. Wine, cafe, tee, marihuana, and cigarettes are not banned, because fun and pleasure (in accordance with nature) are considered as essential for an ethics of holistic well-being or a good life. The consumption of meat and fish is held as ethically appropriate. Hunted game is believed to have "spiritual" powers, and farming of animals must be according to (what technically can be described as) species-appropriate husbandry.

Summary

With the title for the novel Ernest Callenbach coined a name for the sub-genre dedicated to ecological utopias in which *Ecotopia*, with its idealistic impetus and its practical relevance, is the major landmark. Thus, the term Ecotopia

today stands for both, as concept in the discourse on environmentally ethical or ecologically ideal living (e.g., Anderson 2010; de Geus 1999) and for practical endeavors and projects creating ecological optimal and environmentally ethical communities and cities. The novel *Ecotopia* situates organic healthy food and organic sustainable agriculture as integral components in the context of an ideal ecologically envisioned good life and holistic well-being.

Surplus food

Introduction

Edible but unmarketable food is an expression used to refer to food – both processed and unprocessed – that, destined for human consumption, is no longer on the market. In other words, this is food that was originally cultivated, maybe even processed, packaged, and/or transported to habitual sale and distribution points in order to be consumed by an end user, but exits the normal process of commercialization at some stage of said process. In most countries of the world, although more clearly in the countries of the Global North, there is legislation that excludes from the market products that are not *safe* (in the EU, for instance, this is known as the *Hygiene Package*) and, in turn, there is a wide range of technical regulations which specify when food may be

considered to be in this state. It should be made clear that *edible but unmarketable food* fulfils these safety criteria, but becomes unmarketable due to other reasons or circumstances.

The reflection upon these products arises in relation to policies of reduction of food loss and food waste. Strategies on how to avoid food loss and food wastage employ as a reference for decision-making a pyramid which reflects a hierarchy of best practices in reducing food waste and situates at the top levels the best ways to prevent and divert wasted food. Applying the environmental principle of reduction of pollution at source (source reduction), priority is given in this hierarchy to those actions that reduce the volume of surplus food generated and other mechanisms for improving efficiency (FAO 2013).

The second tier of the hierarchy is for actions that, once it proves impossible to keep food in the commercial circuit, seek to contribute to this being used for human consumption, provided – of course – that it is perfectly edible and safe. This exercise of “reuse” or “rescue” involves both developing markets for products which would not otherwise have stayed in the food chain (e.g., unharvested crops or products rejected by retailers but still fit for consumption), and the redistribution of surplus food to people in need. The latter case, insofar as it connects sources which generate surplus food with systems attending to people in need, there is talk of building *food bridges* that attempt to bridge the gap food excess and hunger in our societies (Escajedo San-Epifanio 2016).

In both cases, this reuse involves acting upon edible food (food that is fit for human consumption) but due to differing circumstances (Schneider 2013) is unmarketable. In some cases, these are unsold products that are unsellable due to errors in labelling, short shelf life or packaging errors, or are simply surplus; in others, as mentioned above, the food is unharvested on account of aesthetic damage (parasites, weather conditions), economic reasons (excessively low prices on the market that would not cover harvesting costs, overproduction) or linked to the product’s commercial defects (when it does not meet the minimum quality standards regarding shape, size, etc.).

Reasonableness: The First Filter To Be Passed by Any Action of Reuse

Although, per se, reuse is regarded as a more environmentally friendly practice than food waste, an initial reflection to which any action of reuse must be subjected is its reasonableness, in both economic and environmental terms. Producing food implies an economic cost and an environmental footprint, and upon this premise, it is argued that reuse is more appropriate than food waste, but in some cases, the cost of reuse and its footprint – added to those generated in the production of the food – are excessive. This is particularly notable in cases when reuse or the distribution system are designed and implemented for occasional use.

Furthermore, and also within the analysis of the reasonableness of actions of reuse, it is important not to lose sight of the fact that reuse is in the second tier of the aforementioned pyramid and that the optimum and priority actions to reduce food losses and food waste are those that involve improved efficiency (FAO 2013). Special care must be taken when building bridges between sources of surplus food and people in need. There exists a deep-rooted sense of altruism, its roots not only moral but also anthropological (see in this encyclopedia the entry ► [Food Altruism](#), by Esther Rebato Ochoa) which leads us to regard as more reprehensible waste of food than of other consumer goods (Gjeris and Gaiani 2015). However, recovering food that is no longer on the market is economically and environmentally less efficient than reducing the quantity of this food. It should be borne in mind that reuse involves generating food recovery circuits (with investment in logistics, human resources, and other material resources), and it may prove economically less costly to waste food than to redirect it with full hygiene and health guarantees to organizations that attend to people in situations of food poverty. In the medium and long term, it is to be hoped that people in situations of food poverty can enjoy their human right to food, without having to resort to charity (Elmes et al. 2016), and that the efficiency of commercial chains will significantly reduce the rates of food loss and waste.

Do We Need a Specific Framework to Foment the Distribution of Surplus Food? Challenges and Risks of these Regulatory Frameworks

Since the late 2000s and, particularly, early in the 2010s, at a global level (especially promoted by the FAO) and in different regions of the world, strategies to combat food waste began to be introduced (EU Parliament 2012; Land and Hasman 2016). Altogether they address the question of implementing each and every action that appears in the aforementioned hierarchy which projects the three Rs (reduce, reuse, recycle) and anticipates landfill as a last resort (UNEP 2014). The design of frameworks in this context means establishing political, legal, and administrative measures that might contribute to attaining these objectives, in each tier of the hierarchy. This is not the place to consider them all, but we will concentrate specifically on the measures aimed at promoting the redistribution of food to those in need. Most of these programs, in the EU or the USA, adopt an approach which leads to them being referred to as frameworks that encourage the donation of excess food. There is mention, in some cases, of the donation being made to charitable organizations or the objective being that the food reaches those in need.

Assuming that the reduction of food waste across the EU is essential, some legislative measures seem to be appropriate. But we have to ensure that the legislative measures chosen, though focused upon this objective, are themselves efficient for this purpose and that, moreover, they do not generate other collateral problems. Firstly, one has to analyze whether the attempts to limit responsibility may (or may not) clash with decades of legislative efforts to avoid risks to food safety. It is also necessary to evaluate the extent to which the regulatory framework has the capacity to take into account all the aspects involved in the problem of waste (among them, environmental aspects). And, finally and above all, one must ensure that the regulatory framework does not become an escape via which actors in the commercial food

chain attempt to dispose of their surpluses while eluding any responsibility deriving from the latter (Arroyo Aparicio 2017).

Another important challenge, particularly in the welfare states of the Global North, is that of taking into account the social contexts in which measures for reduction of food waste are being considered. One of the major criticisms of the European system is that of forgetfulness. They omit a profound analysis of the situation of the millions of people (the European Commission estimates the figure to be 55 million (EU Commission 2016)) and of the fact that in a scenario of opulence and very far from other regions of the world that are food insecure, in a scenario of surplus, there are people who are not guaranteed the human right to food. The focus of support for charitable organizations should not be an obstacle to the application, as a hierarchical priority from an ethical and legal point of view, of a human rights approach. In emergency situations, the role of charitable organizations is crucial, but in the medium and long term, societies, especially those whose resources are more than sufficient, must guarantee dignified and autonomous, sufficient, adequate, and stable access to food. Food vulnerability does not receive, at the present time, sufficient attention in the Global North, and there is insufficient awareness of the implications of this for fundamental rights or for public health (owing to the increase being produced with regard to illnesses related to unhealthy diets). It is striking that the reflection upon the measures to improve the efficient use of food in societies is not being combined, in any way, with a reflection upon the problems of those who – in opulent societies – do not have access to food.

Existing Legal Mechanisms to Encourage Donations, from the Perspective of the Donor Agencies

It is true that some draft legislation is being prepared that in the near future may be reflected in EU Member States' laws. But currently here exists no harmonized text in European Law which specifically regulates this area, aside from

food safety laws (Arroyo Aparicio 2015). Thus, by way of basic legal background, one must mention the general regulation in the area related to food safety (Regulation EC 178/2002) and which applies to foods (and feeds) and must be observed by all entities operating in the market, including food banks or nonprofit organizations that handle food. This initial situation was also at the origin of the preparation of a Comparative Study in 2014 (Deloitte 2014), as all food operators must respect at each stage of the chain the legal requirements established in respective areas of responsibility. For this reason, it has been thought that these demands, applicable both within the market itself and outside, may reduce the interest in donating food.

There had indeed been specific legal approaches in some countries, of a very different legal tradition to Europe's, as is the case of the so-called US Good Samaritan Laws (Bill Emerson Good Samaritan Food Donation Act 1996; Haley 2013), which address the problem from the point of view of the donor's responsibility, in a manner that seeks to favor food donation by limiting the responsibility of the donor. In EU countries, meanwhile, first mention goes to the case of Italy, as a law was passed at an early stage in this country, in 2003, which applies to charitable organizations devoted to food distribution. The law, very innovative at the time, regarded these entities as consumers, which implies a lower level of diligence than would be the case if they were classified as food operators. The Italian law was modified in 2016 (Italian Parliament 2016), though the aforementioned comparison is maintained with a broader scope and immersed in a more detailed and wider regulation.

One should also highlight the French regulation of 2016 (French Parliament 2016) which addresses the encouragement of donations from a different regulatory perspective to those already referred to, favoring agreements reached with retail outlets to offload unsalable food in the form of donations.

The aforementioned Study of 2014 analyzed the possibility of also establishing tax incentives as facilitating measures for food donation. It also underlined the fact that the legislation of some countries hindered for example the

commercialization of food past its sell-by or best-by date. In this context, the existence of codes of good practice for food handling is a growing and fairly widespread trend. This is the case in Belgium, where these codes included the introduction of a safe food guide intended to minimize conservation time and the risks associated with conservation prior to donation.

Conclusion

Bearing in mind that the regulations are few and divergent in their approach, it is also apparent that they exclude initiatives or mechanisms that have arisen in reality and are innovative. For instance: foodsharing, solidarity fridges, solidarity Tupperware schemes, etc. It seems clear that these examples do not fall within the activity of economic operators, but rather are private transfer actions that in some cases involve delivery of food and in others, simply, making this food available in a suitable place.

With regard to these activities, the following question might be posed: can they be considered "private use of food" or is it necessary to apply to them the requirements established by regulations for commercial food delivery in minor quantities (retail outlets and establishments intended for the final consumer). There is no one answer, valid for every case. It seems clear that some activities are closer to "private use," others would be classified as actions of charitable organizations, and others, taking into account different criteria (organization, regularity, existence or not for profit, etc.) are nearer to the activities of economic operators. Solutions like self-regulation (by way of a food handling guide) are considered good practice.

Summary

Edible but unmarketable food is an expression employed to refer to food – both processed and unprocessed – that, destined for human consumption, is no longer on the market. Although the exact quantity is unknown, the food in these circumstances (edible but unmarketable) forms part

of the thousands of tons of food that is wasted every year all over the world. This encyclopedia entry addresses the ethical-critical reflection upon the concept of edible but unmarketable food and the different strategies currently being considered to deal with the issue. Among them, the redistribution of surplus food to people in need. In the latter case, insofar as it connects sources in which surplus food is generated with systems that attend people in need, there is talk of building *food bridges* in an attempt to bridge the gap between food excess and hunger in our societies. That task of recovering food faces logistic and economic challenges and poses, in addition, ethical and legal questions that are not being answered in the same way in every country.

Introduction

Like any human food of animal origin, eggs raise ethical issues with respect to safety and quality for human consumption, environmental impact, and duties regarding the animals themselves and with respect to a cluster of social issues associated with the economic structure of the egg industry. Eggs

do have a number of singular features, however. On the one hand, egg production does not strictly require the death of an animal, and eggs are consumed by many people who adopt vegetarian diets for ethical reasons. On the other hand, industrial egg production in the so-called battery cages (discussed below) has been an especially visible target for activists promoting more humane care for farmed animals. Ethical critiques of egg production are also plagued by significant gaps in lay knowledge – the fact that eggs and chicken meat are as distinct from one another in terms of ethical issues as they are from pork or milk production being a leading case in point. This article begins with an overview of the methods being employed in contemporary egg production and moves on to consider first the animal welfare issues, second the human health and environmental issues, and finally social issues associated with the production of eggs.

Contemporary Egg Production

Eggs have almost certainly been consumed by human beings since prehistoric times. Eggs became a household product in conjunction with keeping various bird species in captive or semi-captive conditions for a variety of nonfood-related purposes. Eggs from several bird species have become elements in human diets, but chickens dominate on a worldwide basis. Chickens have been kept in close proximity to human habitations for the purpose of harvesting eggs for centuries, usually in flocks of 10–50 birds, though it has not been unusual for householders to keep a single animal for this purpose. As the modern food system evolved over the nineteenth century, eggs became available from butchers, grocers, and other market vendors, giving rise to commercial production of eggs on farms. Prior to the twentieth century, this production was an auxiliary activity of farm households, with chickens typically kept near the kitchen and fed on scraps. It was not until the 1930s that a commercial industry of farms specializing in production of eggs for urban markets began to evolve (Oesterle 1995).

The first generation of egg farms for large-scale commercial production utilized large open areas with feeding and water stations distributed around the area. Producers developed “deep litter” flooring systems that captured urine and manure. Eggs were gathered by hand. These systems began to be replaced by barns where hens were kept in cages suspended above the floor. These cages were designed with wire flooring that allowed eggs to roll out into a trough, significantly reducing the cost of hand collection of eggs. Eventually, cages were augmented with automated systems for delivery of feed and water, for collection of eggs, and for removal of wastes. These automated systems were most efficiently used when cages are lined up in long rows (or batteries), generally hung from the ceiling of the barn in 3–5 tiers. This became known as the “battery cage” system for egg production. Equipment manufacturers developed many variations of the battery cage, with cages ranging from cubes of roughly 14” or 36 cm on each side to rectangles that could be several multiples of 14”, 36 cm dimension on the side where automatic feeders and egg collection machinery were operating. The battery cage became the most widely used practice in industrialized food economies by the 1970s (Stadelman 1995). As discussed below, it has been a frequent target of criticism on ethical grounds.

Equipment for automating egg collection and feed delivery in floor-based systems has allowed this system to coexist with the battery cage. As a market for “non-cage” or “cage-free” eggs began to emerge in the 1990s, floor-based systems were the main alternative to battery cages. By 2010, several alternative systems had been developed. The aviary system looks a bit like battery cages without doors, but it permits birds free movement within the house. Since birds overwhelmingly prefer to nest and lay eggs in the cage-like niches, the aviary is able to utilize automated egg collection that is very similar to that of battery cages. A third alternative is the “furnished cage” or “colony housing system.” Here birds are kept in cages that are much larger than a battery cage – as much as 10’ or 3 m in length and 6’ or 2.5 m in width. These cages are equipped with nesting boxes,

perches, and scratch areas that are intended to afford the opportunity for performing a number of species-typical behaviors believed to be significant for hen welfare (Mench et al. 2011).

Commercial production of eggs in concentrated animal feeding operations (CAFOs) utilizes all of these systems, typically in ventilated and temperature-controlled (but windowless) industrial buildings of immense size. A commercial egg production facility in any industrialized country will generally operate several of these buildings, which will house between 300,000 and one million birds each. Buildings are generally clustered near a centralized facility for washing and processing eggs and preparing them for sale. Eggs are processed either for sale in the shell (shell eggs) or as liquid or powder (breakers). Other food industry firms (such as bakeries) and institutional kitchens (such as hospitals or hotels) are the primary market for liquid and powdered eggs. As markets have become more specialized, producers have followed suit: most egg farms are geared exclusively to either shell egg or breaker markets (Stadelman 1995). This point becomes ethically significant because farms producing for institutional markets have proven to be far less sensitive to consumer preferences for animal welfare or other ethically significant traits.

Hens for egg production become available through a supply chain that begins with a breeding company that develops a particular strain of bird through genetic selection. Breeding companies have started to use genomics and marker-assisted breeding, but genetic engineering has not had commercial application in the egg industry. Breeding companies may operate their own hatcheries or may license independent owners to produce their strains. Hatcheries maintain a breeding stock of hens and roosters: their product is chicks intended for egg production (Stadelman 1995). (Hatcheries may also produce chicks for meat production, but broiler production is increasingly becoming a wholly vertically controlled process.) In 2013, researchers announced a test capable of discriminating the sex of a chicken embryo (Golovan et al. 2013). Male chicks have no value in the egg industry and are destroyed in macerators within minutes of being born. If

embryonic sexing can be made practical for use in commercial hatcheries, it will end the ethically problematic practice of destroying 50% of the chicks and will save the costs associated with this waste of life.

The methods just described are responsible for an overwhelming majority of the egg production in the industrialized world – perhaps 98% or 99% of all eggs consumed. Eggs continue to be produced in traditional “backyard” settings reminiscent of the preindustrial era. In less developed economies, such production may be consolidated for retail sale much as it was done in the United States, Europe, and other industrialized economies prior to World War II. However, the use of industrial methods described above is growing rapidly in the industrializing world and especially in Asia. There are also egg farmers producing free-range and organic eggs in floor-based or aviary systems on a drastically reduced scale, in flocks ranging from 200 to 10,000 birds. Organic egg production prohibits the use of battery cages and requires both outdoor access and the use of organically produced feed. This segment of the market is growing rapidly in the United States and Europe, but most organic production does not impose limits on scale. Thus, most organic production is done by firms that operate floor or aviary systems at industrial scale, and most of these producers also operate barns producing for the conventional caged layer market. Caged production is under a phaseout in the European Union and should have ended entirely by 2013 according to directives enacted in the early years of the twenty-first century. Reports indicate that compliance with these directives is uneven, however (Mench et al. 2008; Millman et al. 2010).

Health and Environmental Issues

Keeping poultry of any kind can be a contributing cause to unwanted health and environmental impacts. The ethics of egg production must therefore consider why these impacts are taken to be harmful and what measures should be taken to mitigate harm or forestall the occurrence of harm, on the one hand, and the extent to which

unwanted impacts can be viewed as costs that are offset by the compensating benefits of egg production, on the other. After many years of uncertainty over the impact of eating eggs on human health, mainly associated with dietary consumption of cholesterol, the current scientific consensus alleviates that concern (Fernandez and Calle 2010). Unwanted human health impacts include food safety, occupational health and safety, and the role that keeping poultry plays in the transmission and control of communicable disease. Environmental impacts include pollution from manure and any other harmful outputs of the egg production process and the secondary environmental impact of producing and consuming inputs to egg production such as feed, fuel, and water.

Food Safety: Raw eggs are an especially good medium for growth of microorganisms, but the egg’s shell is also a very effective barrier against the initial contamination of this medium. There are thus good reasons to be attentive to egg safety and reasons to expect that an intact shell egg will be an unlikely threat. Removing and destroying broken eggs becomes the primary means for limiting health risks from eggs. Developing control mechanisms within egg production systems that limit damage to eggs and that identify and eliminate eggs with cracked or damaged shells is the key means for doing so. Commercial producers, processors, and retailers have significant economic incentives for maintaining these control mechanisms, and there has been virtually nothing written on this activity that takes an explicitly ethical standpoint in respect to them. Advocates of industrialized egg production assert that mechanization of the process along with the inventory control that mechanization facilitates yields a food safety advantage for industrialized egg production when compared with traditional methods. This assertion has also received relatively little consideration from an ethics perspective.

In statistically rare cases, freshly laid eggs can be contaminated by *Salmonella* apart from any defect in the integrity of the shell. The occurrence is rare enough that definitive research on the phenomena has proven elusive. Data from the US industry shows a greater statistical occurrence of this phenomenon in non-cage production systems,

especially those in which hens are free to roam about on the floor. Data from the European industry has shown just the opposite result. Some investigators have speculated that this difference may arise from the fact that the non-cage production facilities from which data has been collected in the United States tend to be relatively old, while those in Europe are new, many having been placed into production only 1 or 2 years before data was collected. However, others cite the European data as evidence for the inherent superiority of non-cage systems and tend to ignore conflicting data from the United States (Holt et al. 2011). This is, as yet, an issue that could be a topic for future investigation from an ethics or philosophy of science perspective.

Occupational Safety and Other Health Impacts: One US egg producer who was at the center of a controversy over Salmonella-contaminated eggs in 2011 had also been cited for numerous workplace violations. Yet, there is very little to no work on the extent to which egg production can be associated with health or safety impacts for the human beings who are employed in egg production facilities, and any connection between worker health and safety and the methods or corporate culture of egg production is, at the time of writing, purely speculative. Animal production of all kinds has been subjected to ethical criticism for excessive use of antibiotics, and some critics have included egg production. However, there are no economic advantages to be obtained from feeding subtherapeutic doses of antibiotics to laying hens, and egg producers assert that antibiotics are not administered to hens in industrial egg production.

There are also human health issues associated with the role that agricultural animals may play in zoonosis, in this case the crossover between avian and human infectious diseases. Avian influenza (or “bird flu”) would be an example that is familiar to most people. Some speculated that keeping a large number of birds closely confined in an enclosed space provides an ideal opportunity for new infectious diseases to evolve and to cross the species barrier to human workers who are in contact with them (Hinchliffe and Bingham 2008; Nickelsburg 2013). Others have argued that

infectious diseases are much more likely to evolve in non-domesticated species and that contact between chickens and other species of wild birds is a much more likely source of zoonotic disease (Otte et al. 2007). Since great care is taken to protect laying hens kept in industrial facilities from contact with wild bird species, advocates of this perspective believe that traditional production methods, as well as backyard chickens and organic egg production where birds have outdoor access, are much more conducive to zoonosis. What may be of most interest from an ethics perspective is the way that debates over zoonotic disease and egg safety tend to be cited as evidence that bears on the scale and organization of egg production. Animal welfare or socioeconomic considerations may be ethically more fundamental to the reasoning process of individuals who take sides in these health-related debates.

Pollution and Environmental Impact: CAFOs are point sources for air, water, and soil pollutants associated with manures and other animal waste matter. Egg production in CAFOs has incorporated numerous devices to monitor and regulate ammonia levels both within and near buildings. After a decade or more of difficulties in capturing nitrogen from manure, current systems are very effective in capturing, drying, and reusing manure to fertilize soil. As compared to beef, milk, and pork CAFOs, poultry CAFOs and especially caged layer systems with automated manure collection have transformed animal wastes from being pollutants into being a coproduct with significant economic value. Ironically, it is the more traditional non-cage facilities for egg production that are now more strongly associated with animal waste management issues (Xin et al. 2011).

A life cycle approach to evaluating the environmental impact would also include feed and fuel utilization as well as the environmental impact from manufacturing, operating, and disposing of buildings and machinery. As of this writing, life cycle analyses are only now beginning to appear for all phases of egg production. In a further irony from the perspective of those who oppose CAFOs and industrial egg production, the efficiency of feed utilization in these facilities may prove to be the dominant factor in assessing the

more comprehensive environmental costs of consuming eggs in the human diet. Facilities that use feed efficiently require less land and less carbon fuel to produce and transport the grain fed to laying hens. Non-cage systems currently tend to be less efficient both due to loss from the machinery for distributing food to birds and because the systems allow hens to engage in behavior that wastes feed. The efficiency of many traditional systems is lower still for purchased feed, though allowing hens to consume kitchen scraps and to graze on yard grasses may compensate for these inefficiencies (Mench et al. 2011). As with human health impacts (and distinct from environmental issues associated with other animal food commodities), the ethical significance of environmental impacts of egg production may reside in the way that they do or do not augment or offset more fundamental debates over animal welfare and socioeconomic impact.

Hen Welfare

The welfare of hens in egg CAFOs is a signature issue in food ethics. The crowded condition of hens in caged layer systems is one of the most frequently cited problems in ethically oriented critiques of industrial food production. Efforts to address this situation are usually addressed within the framework specified by two of the Brambell Commission's "Five Freedoms": hens should be "free from discomfort" and "free to express normal behavior," (Farm Animal Welfare Council 2009). The lack of space allocated in egg production facilities should not be source of pain or discomfort and should be sufficient to allow for expression of behaviors typical for mature, egg-laying hens. The ethical mandate for limiting pain can be specifically derived from Peter Singer's earliest advocacy on behalf of animals, while the need to express a species-typical behavior might have been grounded in Bernard Rollin's idea of *telos* – a set of genetically based needs and drives that provide the basis for respecting animal rights (Rollin 1981, 1995).

As a practical matter, there have been two responses to crowding. One is to utilize

"cage-free" or "free-range" egg production systems where birds are not physically constrained in the way that they are in the battery cage production system discussed above (Rollin 1995). This approach has been the basis of European directives that have banned battery cages and has been adopted elsewhere as a response to consumer demand for ethically produced eggs. The alternative (and not mutually exclusive) approach has been to specify a minimum space allocation for each hen as one component of an animal welfare standard or guideline. This approach is potentially compatible with battery cage systems and also with the furnished or "enhanced" cage system, also referred to as "colony housing" (Lay et al. 2011).

Space allocation is only one dimension of welfare in egg production. Basic physiological elements include access to food and water and living conditions that are free of ammonia and fecal material – criteria that overlap with environmental impacts. The ability to perform natural or species-typical behavior will also include a bird's access to nesting areas and the ability to sit on perches or perform grooming behaviors such as wing flapping and scratching claws. Not all cage-free or free-range facilities will necessarily be equipped with furnishings that permit these behaviors, nor are they necessarily guaranteed simply by focusing on crowding. Access to the outdoors is a somewhat controversial component of hen welfare. Considered in isolation from other aspects of a hen's environment, outdoor access may not be deeply significant, and if access areas expose birds to attacks from predators, going outdoors can be inimical to survival (Millman et al. 2010; Lay et al. 2011).

Current thinking on the ethics of animal welfare recognizes three broad domains. Standard *veterinary health indicators* of welfare include morbidity and mortality, as well as physiological functions such as respiration, digestion, reproduction (egg production), growth, and development. Pain, discomfort, and correlative indicators of satisfaction or feelings of well-being constitute a set of *cognitive indicators* for welfare, while nesting, wing flapping, and scratching or going outdoors are *behavioral indicators*. A key area of

philosophical debate arises in connection with the interpretation of behavioral indicators. One way of understanding the ethical significance of an ability to perform natural or typical behavior is to presume that birds suffer when they are prevented from doing so. That is, one assumes that hens experience some degree of cognitive discomfort or frustration when their living conditions preclude the performance of an indicated type of behavior. On this interpretation, the ethical significance resides in the experience or feelings of the animal, and the behavior itself is an easily observable and specifiable signal that can be addressed through policy or management. The alternative view is to attribute ethical significance directly to the behaviors themselves, irrespective of whether birds experience frustration or dissatisfaction when they are unable or unwilling to perform them (Swanson 2010).

These contrasting views underlie several points of continuing dispute with respect to current and future initiatives that might be taken on behalf of animal welfare in egg production. Outdoor access is an immediate case in point. Although production systems for eggs that can be labeled as organic require outdoor access, producers often observe relatively little use of outdoor areas, especially when outdoor temperatures are uncomfortably hot or cold. Given the assumption that it is the underlying experience of frustration that makes a behavior ethically important, there is no particular problem associated with this. Birds are in some sense choosing not to utilize outdoor areas, and it is reasonable that their actual behavior indicates a preference for remaining indoors. On the alternative view, a producer would have an ethical obligation to encourage or perhaps ensure that birds *do* use outdoor activities. Failure to do so would be regarded as unnatural and ethically problematic (Veissier et al. 2011).

These two ways of conceptualizing animal welfare have been noted by numerous authors. Peter Sandøe and Mike Appleby have characterized the first viewpoint as *welfarist* because it emphasizes animal feelings and preference satisfaction. The view that sees performance of natural behaviors as intrinsically valuable is what they

call *perfectionist* because it specifies the behavior as something to which a producer (and perhaps the animal itself) should aspire, irrespective of an individual preference (Appleby and Sandøe 2002). Bailey Norwood and Jayson Lusk characterize people who prioritize the cognitive experience as “basic welfarists” and those who value performance of species-typical behaviors as “naturalists.” Norwood and Lusk have conducted empirical research on human attitudes to animal welfare and have noted that some respondents will regard aspects of animal comfort and even survival as relatively unimportant, as long as the animal is living a life that would be comparable to the life that they would lead in a wild or natural setting. For example, such respondents do not regard loss of life from hawks or other predators as particularly contrary to animal welfare. According to Norwood and Lusk’s research on the US population, basic welfarists comprise slightly less than half of Americans, while roughly the same number are naturalists, with the remaining minority being classified as “price seekers” who appear not to value animal welfare beyond the satisfaction of the most basic physiological needs (Norwood and Lusk 2012).

This basic philosophical divide is also relevant to the use of genetic approaches to address welfare problems in egg production. For welfarists, it would presumably be permissible to resolve a problem by breeding animals that were less inclined to the behavioral patterns or needs associated with pain or suffering. For example, hens have a genetically based drive to establish a dominance order (a pecking order), and in small groups they will do so through pecking at each other’s feathers. Once established, this behavior typically recedes, but some individuals persist in feather pecking, and in large groups it may be impossible for birds to establish stable dominance rankings. In any case, in cage-free environments with a quarter of a million birds housed under a single roof, relatively weak birds will be subjected to pecking by so many different animals that they will suffer significant injuries, stress, and cognitive suffering. A potential response is to use breeding to develop birds with much weaker drives to establish a pecking order (Cheng

2010). The welfarist position will presumably offer a strong ethical argument in favor of such genetic strategies, while a perfectionist or naturalist perspective would presumably regard the attempt to remove this species-typical behavior as inimical to the naturalness of the bird's life.

More extreme genetic strategies might substantially alter a bird's basic physiological capabilities. Egg production has provided one example of this with blind chickens, a genetically stable strain of birds that are less inclined toward aggressive behaviors, presumably associated with their lack of sightedness. The blind chicken strategy for addressing welfare in egg production has been discussed in the philosophical literature and has, at this writing, spawned a more extended debate on the Internet. However, blind chickens have never been seriously proposed as a practical or ethically defensible approach for addressing welfare in egg production, and empirical research on blind chickens indicates that their welfare is so compromised by congenital blindness that it is unlikely to ever become a feasible approach in practice. This does not prevent the blind chicken idea from serving as a potentially useful thought experiment, often in conjunction with speculation on the potential for genetic modifications that might eliminate an organism's capability for conscious experience altogether. Such a thought experiment was pursued in connection with meat-producing (broiler) chickens in Margaret Atwood's work of speculative fiction *Oryx and Crake* (Warkentin 2006). Philosophers continue to explore the ethical arguments associated with alternative rationales for addressing animal welfare issues in livestock production through these more extreme forms of genetic modification (Thompson 2008).

Summary

Health and environmental issues, on the one hand, and hen welfare, on the other, provide the general framework in which ethical criticisms of industrial egg production continue to be mounted. The overall ethical evaluation of egg production should also take dietary benefits of egg

consumption and consumer cost into account (Watkins 1995). At this juncture, ethical issues in egg production conjoin with arguments for and against vegetarianism or vegan diets. Public debates as well as critiques within the philosophical literature often overlook some basic socioeconomic and biological elements of egg production when health, environmental, and animal welfare critiques of egg production (especially battery cages) conjoin with these broader themes. It is important to underline the utter separation of meat and egg production in modern industrial agriculture. Critiques of broiler production have their own merits, but the ownership structure of this industry, the production methods, and the breeds of birds that are used have little carryover to a critique of eggs. To note just two instances, the bone breakage that has been observed among broiler chickens does not occur in egg-laying hens, and while broiler production has become highly concentrated, the ownership of egg CAFOs remains more competitive and diverse.

In addition, many vegetarians continue to consume eggs. Ethical evaluation of egg production is thus highly pertinent to the ethical case for vegetarianism. Second, eggs are available in convenience stores and other inner city food outlets. They often are among the healthiest items available at fast-food restaurants. The ability to prepare eggs is widely dispersed and does not presuppose education. As noted above, egg production does not involve the use of antibiotic additives to feed. There are thus a number of reasons to view the ethical analysis of egg production and consumption as having a logical structure that differentiates eggs from other animal food commodities. Animal agriculture is not monolithic, in any case. Industrial producers specialize in one animal product, and the producers of one animal commodity view the producers of other types of animal protein as fierce economic and political competitors. In general, scholarship on ethical issues in all areas of food animal production would benefit from more detailed understanding of the structure of animal industries.

The above survey of ethical issues is not exhaustive. One welfare issue that has been omitted concerns the depopulation of CAFOs, a

process fraught with technical difficulties. Because spent hens are not slaughtered for meat, they have little economic value, and there is little incentive for even the most basic attention to humane killing methods. A second set of issues arise in conjunction with the regulatory framework and the various mechanisms that are being used to organize and influence egg production. Like other animal producers, the egg industry has been targeted by activists and journalists seeking to develop sensationalistic stories – a practice that raises ethical issues itself. As such, there are many topics that can potentially engage future work on the ethical issues that arise in conjunction with industrial egg production.

Introduction

More than 800 million people globally do not have access to sufficient amounts of food on a consistent basis. The emergency food system, also referred to as the emergency food assistance system (by the USDA) or emergency food relief, is part of the private sector’s efforts to address hunger and food insecurity among low-income individuals and families, as well as other vulnerable populations such as seniors and the homeless. As the name implies, programs under this umbrella aim to supply food to people in need *on a temporary and supplemental basis* at no cost. However, in many parts of the world the experience of hunger is an ongoing issue for a large number of individuals, and as such people in need may access emergency food resources on an ongoing basis and rely on these resources as their primary means of accessing food.

In the USA, approximately one in six people, including about 17 million children, do not have

continuous access to enough food to eat to meet their nutritional needs (Coleman-Jensen et al. 2012). Given these levels of poor access many people around the world, including the USA, must rely on emergency food in order to stave off hunger and attempt to meet their nutritional needs critical to maintaining health and well-being. Due to persistent social and economic conditions that continue to make hunger and food insecurity a growing problem in the USA, it is clear that emergency food assistance programs have ironically taken on a regular and ongoing role in food provisioning for many Americans. Soup kitchens and food pantries are the dominant forms of emergency food in the USA. Estimates ranging from 12 to 21 million people in the USA annually utilize these resources to supplement their dietary needs. With continued threats to federal safety net programs such as Food Stamps (SNAP); Supplemental Nutrition Program for Women, Infants and Children (WIC); and the school lunch program, this condition of long-term reliance on emergency food is likely to continue (Nestle and Guttmacher 1992).

Soup kitchens, also referred to as emergency kitchens, breadlines, or meal centers, provide prepared foods for individuals and families to eat on-site. Meals at soup kitchens are typically provided for free, though sometimes clients are charged a low price at some facilities. Soup kitchens are nonprofit organizations and are typically staffed by volunteers and/or run by faith-based organizations. Much of the food and related resources used by soup kitchens are provided through charitable contributions.

Food pantries, on the other hand, are sites that distribute groceries and other food products for consumption off-site, most typically for at-home preparation. The groceries distributed to clients typically include major staple items such as grains, beans, and other proteins, as well as canned fruits and vegetables, among others. Foods are packaged together to include these staple items at most food pantries, though a smaller percentage of pantries provide for consumer choice, where clients “shop” the pantry shelves for preferred items and are not required to take products they do not typically consume. Food

distributions to pantry clients are expected to last for several days.

Both soup kitchens and food pantries are viewed as critical community resources that support low-income individuals’ and households’ dietary needs. The majority of pantry and kitchen clients report high levels of satisfaction with the quality and quantity of foods and services they receive. In addition, there is a great deal of overlap among kitchen and pantry clients, with almost three-quarters of emergency food recipients using two or more resources. At the same time, however, there is ongoing concern among hunger and food policy activists that the gap filled by the emergency food system serves as a pressure valve that diverts energy and concern away from addressing the fundamental structural issues at the root of this persistent problem of hunger in the USA (Winne 2005).

This entry centers on the emergency food system in the USA, with a focus on food pantries and soup kitchens. The key issues of poverty, food insecurity, and hunger, which are the root problems and ultimately form the need for this system, are also addressed here in order to provide some background and context to the practices and understanding of emergency food. In addition, as the quality and quantity of food consumed is fundamental to health and well-being, the issues of health-related outcomes associated with food insecurity will also be briefly discussed in this entry.

Poverty, Hunger/Food Insecurity, and Health

Hunger and access to food in the USA are discussed in terms of food security. Hunger is a frequent condition of food insecurity and involves the involuntary lack of access to food that is linked to the development of malnutrition over time (Cook and Frank 2008). Approximately half of emergency food clients are food insecure with hunger. Food security denotes access to readily available, healthful, culturally appropriate, and safe foods by all people, sufficient to meet the nutritional requirements for an active and healthy

life. Thus, alternatively food insecurity is the condition of insufficient or uncertain availability of these foods or other barriers to acquiring these foods. Food insecurity may result in individuals seeking out foods in ways outside of the conventional food system, including utilizing emergency food supplies. The majority of emergency food recipients identify as food insecure, with approximately half of clients identifying as food insecure with hunger. Recently, the USDA moved to no longer report the number of households that experience food insecurity with hunger. This move has come under fire by food advocates and activists. Joel Berg of the New York City Coalition Against Hunger (NYCCA), for example, states strong opposition to this move discounting the arguments the panel responsible for making this decision proposed, including the issues of measurability and the political nature of the word *hunger* (Wilde 2005). Berg argues that *hunger* in fact is a term that is used broadly and is, or can be clearly defined, and the move to eliminate this language itself is political and an attempt to remove the imagery of severe deprivation. The use of the term is still being debated among policy makers, scholars, and advocates with concern for the conceptual and ethical implications the language of hunger versus food insecurity connotes.

In the USA, food insecurity is regularly measured at local, regional, and national levels (USDA/ERS n.d.). Food (in)security is often measured at the household level and examines both physical and economic access to appropriate foods to meet nutritional needs of all members of the household. The US Census Bureau, through the Current Population Survey (CPS), collects the primary national measurement of food security in the USA. This survey, called the Food Security Scale (FSS), includes 18 questions examining household budget allotted for food, quantity and quality of food available for all members of the household, and instances of reduced food intake for adults and children in the household. The results of the FSS are reported by the US Department of Agriculture's Economic Research Service (USDA/ERS). This data is critical in informing programs and policy related to food access and emergency food support.

Food insecurity is a major health issue, especially among children, with infants and toddlers at particular risk for serious health implications and developmental problems (Cook and Frank 2008). Those making food purchasing decisions for households, most typically mothers, often have to navigate food choice and make tradeoffs such as choosing quantity over quality to prevent family/household members from experiencing hunger. Some of these tradeoffs might include choosing lower-cost energy-dense foods, over higher-priced nutrient-dense whole foods. There is some research that suggests these lower-cost energy-dense foods, which typically are more processed and contain higher amounts of fats and sugars, may contribute to adverse health outcomes. These foods typically are comprised of refined grains, added sugars, and fats, such as pre-prepared and prepackaged convenience foods (Drewnowski 2004).

In addition, people utilizing emergency food resources report more hardship with health and material resources than the general population – reflecting higher rates of poverty. Approximately half of pantry clients and two-fifths of kitchen clients report “fair to poor” health, as compared to a third of the general population. This poorer-than-average health status among emergency food services clients may be a barrier to and a reflection of their access to healthful foods. In addition, often times, mothers and other caregivers may reduce their own food intake in order to provide food for children in the household. This sacrifice on the part of caregivers further compromised their own health status.

In the USA, hunger and food insecurity are closely tied to poverty and consequently to the access to emergency food. This is largely due to the absence of state and federal safety nets and systematic benefits that ensure adequate food supplies to individuals and households, which contrasts with other developed regions of the world, such as many nations in the European Union (Nestle and Guttmacher 1992). These conditions position the emergency food system to be forced to whatever extent possible to attempt to fill the gap left by the lack of federal support for the members of the food-insecure public.

The majority of emergency food clients in the USA report utilizing these resources due to low or fixed incomes. Poverty thresholds in the USA are closely tied to food access and are constructed around the affordability of food based on historical estimates of the amount of funds necessary to purchase a “minimally nutritious diet.” The majority of emergency food clients live at or below 130% of the US poverty line (USDA/ERS n.d.). This threshold is set federally and does not take into account regional differences in the cost of living, including variations in the cost of food, which can differ dramatically by geography in the USA. Thus, urban centers, particularly on the coasts, may face even higher food costs, but see the same benefit levels and thresholds, further comprising food access for these residents.

Emergency Food System

Throughout the period of the 1980s and 1990s, there has been a shift in food policy reducing the level of federally supported food assistance programs while at the same time the number of individuals in the USA requiring food assistance has been on the rise (Nestle and Guttmacher 1992). This erosion of federal level support has shifted the responsibility of food assistance to the state level including the private sector, as mentioned above. Much of the private sector is comprised of volunteer driven community-based and faith-based organizations that work tirelessly to organize and distribute food resources to those in need. However, Nestle and Guttmacher suggest that this shift is highly problematic due to the lack of adequate resources available through the private sector to meet the growing demand of hungry Americans. Furthermore, it has been suggested that the scale of this problem is unconscionable in a country with one of the largest economies in the world such as the USA, further suggesting that the federal government must take a larger role in addressing hunger and food security issues.

Much of the private sector work in emergency food is structured through a distribution system with food banks at the center that administer food and other related goods to local sites – food

pantries and soup kitchens – for consumption by clients (Arnold 2004). Food banks are typically nonprofit organizations and may be independent, though many are part of national networks and partnerships. Food banks developed as repositories of emergency food and were once synonymous with food pantries. However, over time, food banks came to expand their role in the collection of food and shifted away from distributing food to consumers and toward working in collaboration with food pantries – which remained in the role of direct distribution – and soup kitchens. Second Harvest (n.d.) is a national organization, which was founded in 1971 and is the largest hunger-relief network in the USA. It administers a national network of food banks that supplies soup kitchens and food pantries across the USA.

The US government also supplies food to emergency food relief programs through The Emergency Food Assistance Program (TEFAP). TEFAP began in 1981, as the Temporary Emergency Assistance Program, distributing commodity foods, and is now legislated under the Farm Bill of 1990, where it was given its current name. In 2009, federal funding for TEFAP was over 600 million dollars, and the program provided over 700 million pounds of USDA commodity foods to states, to be distributed through local emergency food providers. Over 60 types of food products are made available through TEFAP and these include canned and dried fruits, canned vegetables, fruit juice, dried egg mix, meat/poultry/fish, dried beans, pasta products, peanut butter, rice/grits/cereals, and soups. TEFAP also provides administrative funds to states in order to support the distribution and storage of these food products.

The emergency food system also distributes a great deal of food that would otherwise go to waste in the USA. This food is gathered and distributed by various food rescue organizations and include many donations from corporations. Much of this food, if not donated and distributed through the emergency food system, would end up as landfill. This activity contributes to the emergency food system’s reputation as a food waste prevention option – increasingly part of the identity and mission of many food banks,

which also sometimes are referred to as food rescue organizations (Poppendieck 1998). Food activist Mark Winne suggests that this role of food waste prevention/food rescue should not be such a major part of the emergency food system as it further contributes to serve as a pressure valve and distraction for policy makers and the public in addressing the more pervasive issues that set the conditions for hunger.

While some support for the emergency food system comes from the federal government, the majority of funding, food products, and labor come from charitable organizations and volunteers. Approximately two-thirds of emergency food providers are affiliated with faith-based organizations. A number of these organizations do ask clients to engage in prayer or related religious activities with them while receiving emergency food services. In a report by the USDA/ERS (n.d.), it states that the majority of clients are comfortable with these requests.

In a recent study conducted by the USDA/ERS, 90% of clients reported that they were satisfied with the quantity and quality of the food provided at pantries and kitchens. However, a minority of clients in this study reported experiencing difficulty acquiring needed food at times, mainly due to barriers with transportation.

Soup Kitchens

As noted above soup kitchens are an emergency food resource, which provides prepared, often hot, meals to clients for consumption on-site. Meals are provided to individuals and families in need and typically do not require the provision of means testing or income requirements. Approximately a quarter of kitchen clients visit daily, with just under half visiting 2–5 days per week. Many clients rely on these meals to sustain them for months at a time, while a smaller proportion may rely on kitchens for years.

The majority of the food and labor that supply soup kitchens come from local resources, most often from charitable donations and volunteer support. Most soup kitchens are affiliated with faith-based organizations such as churches,

which provide the facilities for preparing meals as well as the space to serve them to clients. Most soup kitchens are open during weekdays and serve either lunch or dinner, though usually not both. Even though soup kitchens are considered a form of emergency food relief, many individuals rely on them as a regular form of nutrition and sometimes for up to several years. For vulnerable populations, including homeless and the elderly, this may be their only meal of the day.

In the USA, soup kitchens entered mainstream awareness during the Great Depression but have been providing prepared meals to the needy since the nineteenth century. The Humane Society of New York established the first recorded soup kitchen in the USA in 1802. Soup kitchens continued to serve communities, but fell out of popularity during the 1820s as prevailing attitudes toward providing such charitable services shifted toward moralizing concerns related to the destruction of self-reliance among the poor and away from an ethic of providing for material needs of those less fortunate. However, the Great Depression brought on a resurgence of soup kitchens, which grew to feed millions of people during the 1930s.

The USDA/ERS reports that during 2000 there were more than 5000 soup kitchens in the USA, which served nearly a half million meals on a typical day and 173 million meals per year. Furthermore, over one million different individuals were served by soup kitchens in a typical month, with almost a quarter of these participants served being children under 18 years of age. However, most kitchen clients are single adults, the majority of whom are men. Nearly half of kitchen clients identify ethnically as non-Hispanic black, while just over a third identify as non-Hispanic white.

Food Pantries

As described above, food pantries are a community-based emergency food resource that provides food products to households for preparation and consumption off-site, most commonly in the home. The USDA/ERS estimates that approximately 32,000 pantries were in operation

during 2000 and during an average month distributed 239 million pounds of food to over four million different households. This distribution is equivalent to approximately 2.2 billion meals per year.

Recipients of food for at-home use typically are required to meet income eligibility criteria set by the state. Nearly half of those receiving food from pantries are children under 18 years of age, with about a quarter of clients being single adults. Approximately half of pantry clients identify as non-Hispanic white and just under a third identify as non-Hispanic black. Pantry clients may be restricted or limited as to the number of visits per month they may make to a given pantry as directed by the pantry administrators. Of pantry clients, about half visit once a month; however, this is unlikely to reflect actual need, but rather system constraints placed on individuals and households.

The majority of food supplied through pantries is through charitable donations of funds or food products, along with some public funding and distribution of commodity goods as described above. Much of the distribution of this food is through food banks which are centralized locations that process food donations from individuals and organizations, as well as government distributions and coordinate among food pantries across a metropolitan area, region, or state. These organizations themselves are nonprofits and many are affiliated with national organizations such as Second Harvest, as described earlier. These organizations are critical in also rescuing food – the process of coordinating with food manufacturers and retailers to obtain foods that are not suitable for commercial sale but still safe and appropriate for consumption. This process takes an enormous number of volunteer hours in order to sort through foods and ensure it is safe for pantry clients. In many ways this process of sifting through donated food, a good proportion of which is not salvageable, serves the needs of donors as much as if not more than the recipients of this surplus food. Moreover, the energies put into “rescuing” food further serves to divert attention away from the pervasive problems that cause hunger to persist in the USA.

Food pantries distribute foods received from food banks, as well as local donations and purchased food stocks. The typical pantry, as mentioned above, limits visits per household to on average once a month. This is in contrast to the rates of average US households that shop for food at stores approximately twice per week. Clearly the resources available to them limit pantries, but these limitations severely constrain and shape the food access and practices of the communities served. There is a movement to increase the number of possible visits to pantries among administrators, emergency food provider, and food advocates, although the practical constraints of limited resources, space, food, and volunteer labor may remain a barrier for many organizations.

Discussion

Low-income individuals and households use a variety of strategies to meet their food and nutrition needs. However, many depend solely on emergency food system services such as food pantries and soup kitchens over long periods of time due to persistent economic difficulties as well as obstacles in accessing and/or insufficient public safety net programs. While a good number of clients utilize a mix of public and private resources, some clients prefer to avoid or have too much difficulty navigating government benefits and programs and thus solely rely on private sector support. This is highly problematic as the emergency food system is ultimately designed for short-term and periodic use and is ultimately not sufficiently resourced to serve as a long-term solution to hunger and food insecurity.

Emergency food, including food pantries and soup kitchens, along with other charitable activities that support individuals and families struggling with food insecurity may partly decrease the risks of lack of availability and access to healthful foods, but the impacts of these activities can be difficult to measure as they are not systematically evaluated as part of national “safety net” programs such as food-related benefits including the Supplemental Nutrition Assistance Program

(formerly known as Food Stamps) and aid to Women, Infants and Children (WIC), as well as feeding programs like school lunch. Furthermore, with the continual decline in funding and popular support for safety net programs, the emergency system takes on a greater role in feeding the hungry while at the same time serving as a pressure valve distracting the public and policy makers from the social and moral problem of hunger and food insecurity.

In a recent report from the USDA/ERS, it is suggested that more emergency food clients may participate in public food assistance programs if it were easier for these individuals and households to determine their eligibility. For this to be possible, these programs would need to include expanding efforts around outreach and education among clients and providers. However, the researchers from this report do suggest additional research is necessary to further understand how to facilitate the increase of access to these programs.

The USA is a wealthy nation with many resources that could address the persistent problem of food insecurity and hunger in a systematic way. While emergency food is a valuable resource to families and individuals in need, it cannot replace a comprehensive policy intervention that ensures the distribution of healthful foods to all. At the same time, even though there may be as many as 40 million Americans experiencing hunger over the course of a year, the US public has a limited understanding and awareness of the conditions and issues related to food insecurity and hunger. Clearly more research and education must be done to improve understanding among the public in order to build support for the types of policy and program intervention changes that must be made in order to solve the problems of food insecurity and hunger in the USA in a comprehensive manner.

Poverty is a critical factor in hunger and food insecurity. In the USA, unlike other regions of the world, enough food is produced to feed everyone in the country. So it is poverty that remains the greatest barrier to accessing healthy foods for low-income individuals and households in the USA. Currently, efforts to relieve hunger and address food insecurity are dominated by the private

sector, particularly charitable and faith-based organizations addressing these problems in a valuable albeit ad hoc manner, with a great deal of good will but limited resources. However, in the USA, the major obstacle to a more systematic national intervention appears to be a lack of political will in the face of growing neoliberalism in various social sectors including health and social welfare.

Summary

The emergency food system, particularly food pantries and soup kitchens, provide a vital service to up to 70% of individuals and households in the USA that may be at risk for hunger and in need of greater access to healthy foods at some point during a given year. Many of these individuals and household members are low income or elderly on fixed incomes, as well as other vulnerable populations such as the homeless. These groups experience some form of food insecurity due to limited resources and lack of a systematic public safety net program and therefore rely on the services provided by the emergency food system in order to meet their nutritional needs vital to maintain health and well-being. In the USA, more systematic policies and programs must be enacted to both compliment and support the valuable work of private sector emergency food, as well as find definitive and enduring solutions to the major problems of food insecurity and hunger in the country.

Introduction

Environmental pragmatism is a cluster of positions within environmental philosophy that brings ideas from the American philosophical pragmatist tradition to bear on methodological and theoretical issues within environmental philosophy and ethics. Environmental pragmatism began to emerge in the environmental ethics literature in the early 1980s in light of concerns over the ineffectiveness of environmental ethics on environmental policy. Animal pragmatism emerged within animal ethics and philosophy in the early 2000s, bringing pragmatist thought to bear on a variety of human-animal relationships, as well as relationships between conflicting positions on animal ethics.

Environmental Ethics Prior to Environmental Pragmatism

The emergence of environmental ethics as a sub-field of philosophy in the 1970s arose as a rejection of the ability of standard ethical theories to account for the value of nonhuman nature. Conventional ethical theories can be used to understand nature as having instrumental value, for example, when determining that humans are harmed through environmental degradation, or in the judgment of nature to be aesthetically pleasing. Nature, on a standard view, is valuable because it matters to humans. Ethical theories that ground the value of nature, as well as the value of all things, solely in their importance to humans are known as “anthropocentric” theories. According to these theories, only humans have intrinsic value; everything else has extrinsic or instrumental value for us. Reasons given for the intrinsic value of humans differ depending on the theory. For instance, utilitarianism attributes intrinsic value to any being that has the capacity to suffer; deontological ethics attributes intrinsic value to humans based on our rationality and autonomy.

The basic contention of early environmental ethicists is the broad claim that nonhuman nature has intrinsic value. Hence, conventional ethical theories, due to their anthropocentrism, fail to capture the true value of the environment. If these views are inadequate, then new views need to be presented which are nonanthropocentric, that is to say, nature is valuable in itself and that the value of nature does not depend on its importance to humans. While environmental ethicists generally agreed that anthropocentrism did not provide a proper foundation for the value of nature, there are a number of other potential ethical principles that could serve as a foundation for the intrinsic value of nature. For example, according to biocentric theories, individual life forms, regardless of their possession of sentience, rationality, or autonomy, possess intrinsic value. According to ecocentric or holistic ethical theories, intrinsic value lies not in individuals, but instead in ecosystems or biotic communities as a whole. Philosophers such as Holmes Rolston, III, J. Baird Callicott, and Paul Taylor engaged in

scholarly debates over which kind of non-anthropocentric ethical theory was the true foundation for the intrinsic value of the environment.

Given the connections existing between environmental ethics and the environmental movement, these theoretical positions were intended to provide a basis for stronger environmental policies by providing arguments for the intrinsic value of nature. However, while the field of environmental ethics has flourished on a theoretical level within academia, many of its key figures have lamented the relative ineffectiveness of the field in regard to contributing to increased interest in and protection of the environment outside the academy. It is here that environmental pragmatism gained traction within environmental ethics as a way of increasing the field's relevance.

American Pragmatism in Environmental Ethics

Though environmental ethics diverged from conventional Western ethics in its defense of the intrinsic value of nonhuman nature, it retained important similarities to theories such as utilitarianism and deontology in terms of its emphasis on foundationalism. American pragmatism rejects the idea that such foundations are necessary for ethics; instead it emphasizes context and situatedness. Rather than developing a fully formed ethical theory in the abstract and then applying it to particular concrete situations, pragmatism favors a case-based approach where an ethical principle may be applicable in some cases but not in others. Rather than arguing for and defending a certain set of principles and sticking to it regardless of the circumstances, pragmatism is geared toward finding solutions in a situation. Pragmatism recognizes that the world is dynamic, rather than static, and calls for a way of doing ethics that takes this into account as well.

Weak Anthropocentrism

Bryan G. Norton is one of the first philosophers to bring ideas from the pragmatist tradition to bear on issues within environmental ethics. Norton's 1982 papers "Environmental Ethics and

Nonhuman Rights" and "Environmental Ethics and the Rights of Future Generations" convey his doubts regarding the possibility of deriving an environmental ethics from the rights or interests of nonhumans as well as future generations of humans, respectively (Norton 1982a, b). In 1984, Norton introduced the concept of "weak anthropocentrism" to the environmental ethics literature (Norton 1984). In a pragmatic turn, weak anthropocentrism entails a rejection of the dichotomy between anthropocentrism and non-anthropocentrism that has been perpetuated by environmental ethicists, as well as the alleged necessity of providing nonanthropocentric arguments for the value of nonhuman nature.

Norton distinguishes weak anthropocentrism from "strong anthropocentrism" (Norton 1984). Strong anthropocentrism is the view that felt preferences of human individuals are the determinants of value, and this is essentially the view which has previously been referred to simply as "anthropocentrism" and which has spurred the development of environmental ethics as providing an alternative to it. Because strong anthropocentrism takes the value of nature to rest solely on the satisfaction of human preference, this view can be used to justify the exploitation of nature with no ethical recourse.

In contrast, weak anthropocentrism provides a basis for criticizing purely exploitative actions toward nature by recognizing the strong ties between humans and other species (Norton 1984). As Norton writes, "[t]o the extent that environmentalists can show that values are formed and informed by contact with nature, nature takes on value as a teacher of human values" (1984). So, while strong anthropocentrism implies that humans simply develop or construct values and then impose these on nature, weak anthropocentrism essentially views the relationship between humans and nature as being part of a feedback loop, where nature itself "becomes an important source of inspiration in value formation" (Norton 1984). Norton goes on to argue that weak anthropocentrism can lead to the development of "powerful" reasons for protecting nature which are distinct from the strictly exploitative reasons for protecting nature provided by strong anthropocentrism (Norton 1984).

The Convergence Hypothesis

Norton continued to flesh out his pragmatic view of environmental ethics throughout the 1980s and first formulated the “convergence hypothesis” in his 1986 article “Conservation and Preservation: A Conceptual Rehabilitation.” According to Norton’s convergence hypothesis, “. . .if the interests of the human species interpenetrate those of the living Earth, then it follows that anthropocentric and nonanthropocentric policies will converge in the indefinite future. Showing respect for nature, its processes of life, may just be an alternative formulation of the injunction to show concern for resource stability essential to human survival over the longest term” (Norton 1986). On this view, whether a person takes nature to have intrinsic value or strictly instrumental value based on human interests, these two views will generally lead to the same positions on policy regarding protection of the environment. The convergence hypothesis has been revolutionary and controversial in environmental ethics because it challenges the view that environmental ethicists should be focused on articulating arguments in defense of the intrinsic (versus strictly instrumental) value of nature.

The convergence hypothesis is an excellent example of pragmatist modes of thought in its rejection of absolutism. For example, it may ultimately be the case that nonhuman nature *does* have intrinsic value, which is nondependent on human interest, or even on the interest of any sentient beings. At the same time, environmental policies are developed and evaluated by humans and are often dependent on human interests. While environmental ethicists may (or may not) have done an exemplary job in getting closer to the ultimate nature of reality regarding the value of nature, their arguments have been largely impotent at a policy level because many of the people responsible for environmental policy are more interested in the value of nature for humans.

Environmental pragmatism then raises the question of what it means to do philosophical work regarding the nature of value. It may, on this approach, be more important, even for philosophical purposes, to suspend metaphysical questions regarding the nature of value if the time spent pondering these questions detracts from the

influence of environmental ethics on public policy. If Norton’s convergence hypothesis is true and an anthropocentric view of value leads to advocating the same courses of action as a nonanthropocentric view, then it may be well worth it for philosophers to dedicate their time and philosophical expertise to articulating the most persuasive arguments in favor of environmental protection. If the most persuasive arguments in favor of this happen to be anthropocentric in nature, then, from the perspective of environmental pragmatism, this should be accepted in order for environmental ethicists to be as effective as possible.

Methodological and Historical Environmental Pragmatism

While environmental pragmatism’s beginnings placed heavy emphasis on the importance of practicality within environmental ethics in keeping with the pluralistic nature of pragmatism, a variety of views have been articulated as part of environmental pragmatism. Andrew Light, for example, makes a basic distinction between “metaphilosophical” or “methodological” environmental pragmatism and “historical” environmental pragmatism (Light 2004). Methodological environmental pragmatism consists of a critique of the methodology of environmental ethics, such as the aforementioned emphasis on the importance of environmental ethicists focusing on practical matters rather than becoming mired in strictly metaphysical questions which are removed from and have little bearing on concrete environmental issues. Light argues that this does not necessarily entail that environmental philosophers completely give up the largely theoretical questions that spurred the development of the field but that they “. . .must accept the public task as well, which requires that they be willing to translate their philosophical views about the value of nature, when necessary, into terms more likely to morally motivate policy makers and the general public even when they themselves have relied on nonanthropocentrism to come to their views about the value of nature” (Light 2004).

While methodological environmental pragmatism draws implicitly from the American

pragmatist tradition due to its pluralist and democratic framework, historical environmental pragmatism explicitly brings particular aspects of the theories of pragmatists such as James, Pierce, and Dewey to bear on environmental issues and environmental philosophy. For example, Robert C. Fuller has argued that William James' provision of the scientific and evolutionary foundations of philosophical pragmatism can be used to understand the connection between the fulfillment and well-being of individuals and that of ecosystems, as well as the spiritual importance of conduct toward the environment (Fuller 1992). Piers H. G. Stephens and Jason Scott Robert have also done work on applying James' ideas to environmental philosophy, while Anthony Weston and Hugh P. McDonald have concentrated on the importance of the work of John Dewey for environmental philosophy (Stephens 2009; McDonald 2002).

In addition to Light's distinction between methodological and historical pragmatism, in their seminal 1996 anthology *Environmental Pragmatism*, Andrew Light and Eric Katz point to four major ways that pragmatist ideas have emerged within environmental philosophy. These include an analysis of the connections between American pragmatist philosophy and environmental issues; the articulation of strategies for linking environmental theory with practice, including activism and environmental policy; the examination of the normative theory undergirding particular environmental organizations in an attempt to work toward compromise and agreement between them; and arguments for pluralism in environmental theory (Light and Katz 1996).

Criticisms of Environmental Pragmatism

Criticism of Ethical Pluralism and the Convergence Hypothesis

A number of criticisms have been leveled against environmental pragmatism despite its popularity within environmental philosophy. J. Baird Callicott has been one of the most outspoken critics, arguing against ethical pluralism in favor of monism for the sake of having a consistent ethical theory (Callicott 1990). Callicott argues further that this monism should be based on

work done within evolutionary theory and the natural sciences (Callicott 1995). While one may appeal to a variety of concepts (such as "God, creation, and stewardship") which may be more persuasive in particular cases for drawing support of environmental policy, Callicott does not grant that these are legitimate reasons due to their lack of scientific basis (he points out that anthropocentric values are economic in nature and must compete with other economic values which are related to the exploitation of nature, arguing instead that appeals to the intrinsic value of nonhuman nature may stand a better chance of success). Callicott has also attempted to show that Norton's convergence hypothesis is false by using the Endangered Species Act of 1973 as an example of a policy based on nonanthropocentric intrinsic value that would have been markedly different if it had instead been based on anthropocentric instrumental value (Callicott 2009).

Criticism of Environmental Pragmatism as a Philosophical Position

In his article "Environmental Pragmatism and Environmental Philosophy: A Bad Marriage!," Lars Samuelsson argues that, given that the nature of philosophy entails examining theoretical questions such as the potential for nature to possess intrinsic value, a position such as environmental pragmatism is actually not a philosophical position at all (Samuelsson 2010). Environmental pragmatism brings with it the assumption, according to Samuelsson, that environmental philosophers should be concerned with "saving nature" and making arguments that address public concerns and aim to affect environmental policy. Samuelsson recognizes the "theoretical merit" of being dispassionate and unbiased regarding the subject matter of one's area of research and argues that environmental philosophy should leave open the possibility that people working within this field do not necessarily have a bias toward arguing in favor of environmental protection of any sort (Samuelsson 2010). Environmental pragmatism threatens to undermine the philosophical goal of getting clear on "the problems that puzzle us," and many of the concerns of environmental pragmatists are best left to practitioners of more empirical fields of study (Samuelsson 2010).

Criticism of Methodological Environmental Pragmatism

Mark A. Michael parses out three different positions within methodological pragmatism and provides a critique of the alleged importance of methodological pragmatism for environmental philosophy. According to radical methodological pragmatism, environmentalists should give up on the task of providing well-founded theoretical grounding for environmental policy and focus strictly on connecting policy with values that people already have (Michael 2012). Moderate methodological pragmatism advocates that it is okay to work on theoretical grounding for environmental values but that differences regarding this should be put aside to work together to affect policy. Weak methodological pragmatism is the view that “environmental philosophers should work together where their policies coincide and there are no additional practical or moral considerations that might be relevant their ability to work together” (Michael 2012). Michael goes on to argue that radical and moderate methodological pragmatism are fundamentally flawed and that, while there are not significant objections to weak methodological pragmatism, the view is largely trivial (Michael 2012).

Animal Pragmatism

Recently, a number of scholars have begun to examine pragmatist approaches to animal ethics and to the relationship between human and non-human animals, resulting in the development of the tradition of animal pragmatism. This new area has taken a variety of forms, assessing issues such as the use of animals in food production, animal advocacy, the tension between animal and environmental activism, biomedical research on animals, and the relationship between humans and pets and other companion animals. In their introduction to *Animal Pragmatism*, Light and McKenna remark on the questionable relevance of the field of animal ethics in terms of its overall impact on the current industrial agricultural system and look to American pragmatism as a philosophical area that may be able to contribute to practical concerns regarding the treatment of farm animals (Light and McKenna 2004).

Pragmatism on Animal and Environmental Advocacy

Light looks at ways in which methodological pragmatism can be applied to issues regarding the treatment of animals. For example, the implementation of “humaneness” as a criterion regarding the removal of “pest” animals from ecosystems which they threaten is a clear point of convergence for environmental and animal advocates, where few environmentalists would completely reject the need to treat animals as humanely as possible even if some action should be taken for the sake of ecosystems (Light 2004).

Pragmatism and Animal Welfare

Paul Thompson contemplates animal welfare scientist David Fraser’s criticism of the field of animal ethics as being too exclusively concerned with abstract theoretical issues regarding the treatment of animals (Thompson 2004). While many of the issues tackled by animal ethicists such as Tom Regan and Peter Singer do have real-world implications, there is an immense shortage of animal ethicists who are well versed in particular technical practices, which are staples of industrial agriculture. Also, while Regan, Singer, and others have been very vocal regarding the promotion of vegetarianism, fewer philosophers have looked at ways to improve the lives of farm animals and what criteria could be used to signify such improvement. Thompson looks to the philosopher Bernard Rollin as an example of someone undertaking a pragmatic approach to farm animal welfare, though Rollin does not identify explicitly as being influenced by the American pragmatists (Thompson 2004).

Rollin brackets the question of whether or not animals should be used in food production and instead accepts that they are and then looks at specific ways that animal lives can be improved (Rollin 1995). For example, in his book *Farm Animal Welfare*, Rollin catalogs a number of standard procedures regarding animal treatment in industrial agriculture, such as debeaking chickens and castrating cattle, and suggests ways that these methods can be made more humane to increase animal welfare, sometimes arguing that certain practices should be discontinued entirely due to being harmful and unnecessary (Rollin 1995).

Rollin's specific ethical prescriptions are undergirded by his adaptation of the concept of *telos* (from Aristotle) to the field of animal ethics. As Thompson writes, "...animal telos is intended to reflect the biological and functional needs that would be characteristic of a given species. Thus, if pregnant sows experience a drive for nesting behavior, this will be characteristic of the pig telos" (Thompson 2004). Rollin's idea is that treating an animal in such a way that it can fulfill its telos will generally result in higher welfare.

Pragmatism and Animal Use in Research

Todd Lekan applies pragmatist thought to the use of animals in biomedical research. He looks for ways to balance the interests of scientists who use animals for research and advocates who work for animal welfare organizations. The dialogue and compromise that Lekan advocates is indicative of the pragmatist emphasis on the development of science, which is informed by public interests through communication between members of the scientific community and laypersons. One way that Lekan proposes to mend the gap between animal advocates and scientists using animals in research is by necessitating the inclusion of animal advocates on institutional animal care and use committees, or IACUCs (Lekan 2004). IACUCs evaluate proposals for research projects, which include the use of animals in various capacities. However, at this time there is no legal requirement for animal advocates to serve on these committees (Lekan 2004). The absence of such a requirement leaves open the possibility that research projects may be approved, which potentially allow for low levels of welfare regarding animals used in such projects. By proposing the required inclusion of animal advocates on IACUCs, Lekan hopes to work toward the achievement of a "middle ground" between abolition and the use of animals in research (Lekan 2004).

Pragmatism and Companion Animals

In her 2013 book *Pets, People, and Pragmatism*, Erin McKenna examines the ways that American pragmatist philosophy can enhance understanding of the relationship between humans and their pets and companion animals. Drawing from her own

life experience and devoting entire chapters to horses, dogs, and cats, respectively, McKenna utilizes the pragmatist ideas of naturalism, pluralism, developmentalism, experimentalism, and fallibilism to develop subtly nuanced positions on a variety of human-animal interactions, such as the use of animals in breeding, research, competition, and work, ownership of animals, and dealing with the death (or impending death) of one's companion animals (McKenna 2013). While many animal and environmental philosophers drawing from American pragmatism focus on the work of Peirce, Dewey, and James, McKenna addresses (in addition to these) the ideas of Jane Addams, Charlotte Perkins Gilman, and Alain Locke as they are applicable to human-animal relationships (McKenna 2013).

Though McKenna's arguments and conclusions are subtle and complex, she argues against the outright rejection of human-animal relationships that is taken by some of the more radical animal advocates and philosophers in favor of a view that sees many human-animal relationships as having the potential to be mutually beneficial, rather than necessarily involving the exploitation of animals on the part of humans (McKenna 2013). Often, the moral permissibility of particular human-animal relationships depends on a number of context-specific particularities. For instance, some horses genuinely enjoy engaging in certain types of competitions, while others may not be physically and psychologically suited for competition (McKenna 2013). McKenna writes that "[a]s long as one has appropriately matched the activity with the physical and psychological abilities of the horse and is able to work with the particular personality and interests of the individual horse (respect the *plurality* of horses), there is not *inherently* wrong with these activities from the Pragmatist point of view" (McKenna 2013, emphasis in original).

Regarding the death of companion animals, it is important to understand and to respect the nature of the animal as much as possible and not to let this respect be overridden by human desires, such as the urge to keep an animal alive as long as possible. Given the evolutionary history of humans and companion animals (especially dogs), it is

important for ethical reasons to take into account the fact that these relationships are mutually transformative rather than unidirectional.

Summary

Environmental and animal pragmatism both incorporate ideas based in the American philosophical pragmatist tradition and emerged due to concerns over the ineffectiveness of animal and environmental philosophy in affecting policy and addressing concrete issues. This entry traces the historical development of environmental pragmatism and the differing views that comprise it, as well as some of the criticisms leveled against it. The recent emergence of animal pragmatism is also discussed, as well as several ways in which American philosophical pragmatism has been brought to bear on specific issues within animal ethics.

Environmental Ethics

Jozef Keulartz and Michiel Korthals
Applied Philosophy, Social Sciences Group,
Wageningen University, Wageningen, The
Netherlands

Introduction

The development of environmental ethics was inspired by the widespread perception of an “environmental crisis” in the 1960s. Rachel Carson's landmark book *Silent Spring* (1962), which documented the accumulation of dangerous pesticides and chemical toxins throughout planetary

food webs, played a vitally important role in raising awareness of this crisis. Never before and since has a book been so successful in providing impetus for action against a common threat to so diverse a body of people.

Silent Spring was published 1 month before the Cuba missile crisis and owed its worldwide success at least in part to Carson's comparison between the effects of atomic radiation and those of synthetic chemical pesticides. By framing pesticides as another form of fallout, Carson's book made a powerful impression on a generation that grew up under the shadow of nuclear destruction. It brought about the transformation of the earlier conservation movement into a worldwide environmental movement.

An important milestone in the emergence of environmental ethics was the first Earth Day on April 22, 1970, when environmentalists started urging philosophers who were involved with environmental groups to think through the norms and values that lead to environmental problems, as well as the norms and values that are necessary for resolving them.

Anthropocentrism and Non-anthropocentrism

In its early stages, the debate among academic philosophers on environmental issues was strongly stimulated by Lynn White's seminal article "The Historical Roots of Our Ecological Crisis." In this article from 1967, White claims that Christianity, as "the most anthropocentric religion the world has seen" (p. 1205), is to be blamed for the ongoing exploitation and degradation of nature in the occidental world. Richard Routley (1973), in another highly influential article, also identifies anthropocentrism, or basic human chauvinism, as the core principle of Western ethical systems and argued that it is inconsistent with a true environmental ethic. A thoroughgoing environmental ethic would reject the anthropocentric principle of total use, "implying that every natural area should be cultivated or otherwise used for human ends, 'humanized'" (p. 206).

In the footsteps of authors such as White and Routley, environmental ethics developed primarily as a radical critique and correction of anthropocentric ethics. There are at least three main approaches to radical non-anthropocentric environmental ethics: Arne Næss' deep ecology (1989), in which the current environmental crisis is attributed to modern humanity's anthropocentrism; Murray Bookchin's social ecology (1995), which explains hostile behavior toward nature in terms of the existence of hierarchical relationships among human beings; and ecofeminism (see Merchant 1983), which points to androcentrism rather than anthropocentrism as the main culprit and assumes a strong relationship between suppression of nature and of women. It is interesting to notice that this discussion has made it very difficult to reconcile environmental ethics with an agricultural perspective, because the latter, necessary for survival and quality of human life, has a clear anthropocentric focus.

An important goal within this field has long been to find a convincing theory of the intrinsic value of natural entities. The debate focuses on whether this noninstrumental value of nature has a subjective or an objective character. Subjectivists claim that the only sources of value are the evaluative attitudes of humans, whereas objectivists (such as Routley) deny that value depends on the attitude of valuers (O'Neill 1992).

The Expanding Circle

Another important debate within the new field of environmental ethics concerned the question of which entities possess intrinsic value. Here the idea of the so-called expanded circle proved to be important, i.e., the idea that humans' moral development is characterized by a constant extension of the moral community (Nash 1989). In the beginning, the circle of beings considered morally relevant was confined to fellow tribesmen, but in the course of history, this circle gradually expanded until all of humanity was encompassed, a milestone reached during the Enlightenment in the declaration of human rights. At first these

rights only applied to male proprietors, but this gradually changed during the nineteenth century, with the abolition of slavery, the emancipation of the laborer, the introduction of female suffrage, and the ban on child labor.

As discussed below, the moral community once again experienced a powerful expansion during the twentieth century and now extends to future generations. However, the expansion of the moral community did not come to a halt at the human species boundary, but also continued, step by step, outside the domain of humankind, first to animals (zoocentrism), next to plants and micro-organisms (biocentrism), and finally to collectives such as endangered species and complete ecosystems (ecocentrism).

Transgenerational Ethics: Past and Future Generations

In reaction to the emergence of environmental problems on a global scale, the moral community recently underwent a powerful extension to future generations. This expansion of the moral community is evident in the 1989 Brundtland report *Our Common Future*, in which sustainable development is defined as “development that meets the needs of the present without compromising the ability of future generations to meet their own needs.” Present generations are obligated by considerations of (distributive) justice not to pursue policies that create benefits for themselves but impose costs on those who will live in the future.

The Brundtland report mentions not only justice *between* generations (intergenerational justice) but also justice *within* generations (intragenerational justice) as preconditions for sustainable development (see also “► [Sustainability of Food Production and Consumption](#)”). For example, there is a huge difference between the rich North and the poor South with respect to the consumption of natural resources. This difference can be visualized with the help of the so-called ecological footprint (“EF” for short) (Wackernagel and Rees 1996). The EF is a measure of human demand on the Earth’s ecosystems that indicates how many hectares of productive

land and sea area an average person needs for his or her consumptive activities on an annual basis. The present footprint of inhabitants of poor countries is far below the global average of 2.2 ha, whereas the footprint of those of rich countries is far above this average.

A bone of contention with respect to sustainability lies in how far nature’s services can be viewed as resources that are substitutable (in the sense that it is acceptable that when one destroys one and leaves another intact) or not: the first view is called weak sustainability and the second view strong sustainability (Norton 2005). Weak sustainability allows for virtually unlimited substitution between man-made, manufactured capital, which incorporates resources such as infrastructure, labor, and knowledge, and natural capital, which covers the stock of environmental services. The decline of natural capital can be compensated by an increase of manufactured capital. Intergenerational equity is guaranteed as long as the total capital is left constant over time. Strong sustainability on the other hand denies that man-made and natural capitals are interchangeable, implying that natural resources should be passed to future generations still intact in their original form.

People have duties not only to future and current generations but also to past generations. One should pay honor and respect to the dead. That means remembering their achievements, continuing their work, or paying compensation to their children for a wrongdoing they may have suffered. Transgenerational ethics can underpin the notion of “cultural heritage.” Of course, these retrospective, present, and prospective duties can conflict with each other.

Zoocentric Ethics: Utilitarian and Deontological Perspectives

In his 1840 *Preisschrift über die Grundlage der Moral* [*On the Basis of Morality*], Arthur Schopenhauer remarked, much to his regret, that above the entrance of occidental ethics hangs a prohibition sign with the inscription: “Tiere müssen draußen bleiben” [Animals have to stay outside].

One of the first modern philosophers who successfully denounced this situation was Peter Singer. Singer (1975) blames traditional ethics for the fact that animals are wrongly excluded from the moral community. Traditional ethics attributes a superior moral status to humans on the basis of their exclusively possessing specific capacities like the ability to think or to speak. If this criterion were applied rigorously, however, then newborn children and demented people would not deserve any moral consideration. If one wants to avoid this consequence, then one has to choose a less demanding criterion for right of entry to the moral community. Singer borrows this criterion from Jeremy Bentham, the famous founder of utilitarianism. "The question is not," Bentham stated in 1789, "Can they reason? Nor Can they Talk? But Can they *suffer*?" If one accepts the ability to suffer as the main criterion for right of entry, then there is no reason to exclude animals from the moral community.

Singer argues that one should engage in actions that result in the greatest good for all sentient organisms. Thus, in the utilitarian calculus, the damage to animal welfare has to be weighed against the human benefits of food, shelter, medicine, and so on. Animal experiments can, for instance, be justified on utilitarian grounds if substantial human health interests are at stake which outweigh the harms to the animals and when there are no alternatives that produce a greater net balance of benefit over harm.

Tom Regan has strongly rejected utilitarianism as foundation of animal ethics. In his influential 1983 book, *The Case for Animal Rights*, Regan develops a theory of animal ethics along deontological lines. According to Kant's categorical imperative, one should treat fellow humans never merely as a means, but always at the same time as ends-in-themselves. Tom Regan has applied Kant's categorical imperative to animals. Animals should not simply be appreciated for their instrumental value but they should be respected for their inherent value. To achieve this, one should grant animals certain rights, according to Regan. These rights prevent trade-offs between animal welfare considerations and human welfare considerations. For Regan, virtually any type of captivity or

manipulation of a sentient animal is morally unacceptable, irrespective of the possibly beneficial consequences for the protection of rare or endangered species.

Although most animal ethicists only attribute moral standing to individual animals, and not to plants or collective entities such as species or ecosystems, they are nevertheless convinced that animal ethics is an environmental ethics, because individual animals can survive and flourish only if they have a sustainable and sound environment.

Biocentric Ethics: Egalitarian and Hierarchical Approaches

The next step, the transfer of ethical fundamentals from human beings to plants and microorganisms, was taken by Paul Taylor, who was influenced by Albert Schweitzer (1923) and his "reverence for life" ethic. Taylor (1986) defends a biocentric position, implying that not only humans and animals should count as members of the moral community but all living beings, including plants and microorganisms. Without exception, all organisms deserve moral consideration because as "teleological centers of life," they have a good of their own. This good consists in the realization of capacities and the fulfillment of needs in a regular, well-balanced way that goes with the species-specific nature of organisms. According to Taylor, human beings can claim no primacy over other living beings. On the basis of his "principle of species impartiality," all organisms should be treated with equal care and respect, regardless of the species they belong to. However, not all biocentric approaches are egalitarian and consider all organisms to be equal. Hierarchical approaches make an organism's value dependent on their organizational level; they will generally attribute higher value to animals than to plants.

Endangered Species and Biodiversity Protection

While some people would dispute whether ethical obligations exist to protect or prevent harm to

individual organisms, many more are willing to acknowledge that it is morally wrong to jeopardize the continued existence of an entire species. This has become a particularly central issue in public land-use policy as urban development and habitat loss have increasingly become major causes of species extinction.

Much of the reasoning used to justify concern about loss of endangered species in recent years has clearly been anthropocentric in nature. There are many important pragmatic reasons for protecting endangered plant and animal species (see also “► [Biodiversity and Global Development](#)”). They represent a tremendous biological storehouse, the loss of which may deprive us of substantial medical, scientific, and commercial benefits. But non-anthropocentric arguments have also been offered. Similar to the positions embraced by animal rights supporters, the protection of species diversity is sometimes defended on the grounds that species have an inherent right to exist regardless of the utility or value such species might hold for humans (Rolston 1986).

Ecocentric Ethics: Land Ethic Versus Animal Ethics

Both Singer’s utilitarian (animal welfare) approach and Regan’s deontological (animal rights) approach center on individual organisms, the difference being that Singer allows for utilitarian trade-offs between the various interests of individuals. The same holds for biocentric approaches. For both zoocentrists and biocentrists, collectives (e.g., endangered species) do not possess any intrinsic value or direct moral standing at all. This individualistic approach was opposed by philosophers who felt that the narrow focus on individual welfare failed to address the concerns of environmentalists about pollution, biodiversity loss, habitat fragmentation, and so on. They advocated a holistic approach in which organisms are perceived as parts of a greater whole such as biotopes or ecosystems. The *locus classicus* of this holistic approach is *A Sand County Almanac* (1949) by

Aldo Leopold (1887–1948), a famous nature conservationist who was strongly influenced by the science of ecology. The basic moral rule of his so-called land ethic goes as follows: “A thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is wrong when it tends otherwise” (Leopold 1949, p. 262).

Around 1980, a fierce conflict erupted between individualistic animal ethicists and holistic environmental ethicists. Tom Regan maintained that as long as proper respect was shown for the rights of individuals, the biotic community would also be preserved, simply because this community is ultimately made up by individuals. Environmental ethicist Baird Callicott (1980) depicted this conviction as a certificate of “ecological illiteracy.” Animal ethicists make no distinction whatsoever between wild and domesticated species, between rare and common species, and between native and exotic species. According to Callicott, the moral worth of individuals is relative to be assessed in accordance with their particular relation to the collective entity which Leopold called “the land.” Tom Regan responded to this attack with the accusation that environmental ethicists were committing the crime of “environmental fascism” by subordinating the rights of individuals to the interests of the greater whole. “Environmental fascism and the rights view are like oil and water, they don’t mix” (1983, p. 362).

Eight years after his frontal attack, Callicott (1989) offered individualistic animal ethicists an olive branch. As a compromise, he proposed to order one’s moral relations according to concentric circles. He now made a distinction between three different communities: the human community, the mixed community of humans and domesticated animals, and, finally, the wider biotic community that also includes wild animals. This attempt to reconcile individualistic animal ethics and holistic ecoethics through a theory of concentric circles comes down to a division of labor between three moral regimes: traditional, anthropocentric ethics is about humans and their relations to each other, zoocentric and biocentric ethics are about the well-being and the integrity

of domesticated and cultivated species, and ecocentric ethics deals with wild species as members of the biotic community and as parts of the ecosystem.

Climate Change and Global Justice

A new impulse for environmental ethics is the all-pervasive problem of climate change. It permeates everyday actions in the West, such as eating meat and driving a car. It challenges environmental approaches to find the causes of climate change and, as a consequence, the proper allocation of responsibility for human actions that increase climate change. Responding to climate change requires huge investments in new technologies both to moderate and to accommodate climate change, and the main issue here is who is to bear the burden? (see also “► [Climate Change, Ethics, and Food Production](#)”). Consider an issue that was already implicitly mentioned in the discussion about sustainability: is it ethically acceptable to put price tags on natural services to make clear what damage is being done and what repairs should be done? On various levels, the issue of “monetization” or commodification plays a role: rich countries, for example, can satisfy their duty to compensate for increasing climate change by investing in climate neutral technologies in poorer countries, or individual countries can charge climate changers to pay for their role in climate change. Many will argue that this type of commodification is inappropriate, given the intrinsic value of nature, and that paying a price means degrading the climate as a common good; finally it motivates the rich to continue with their conduct and not to look after more sustainable patterns of behavior. There are also other arguments against pricing, including the fact that pricing requires a strict analytical approach to exactly delineate which elements and particular services of the environment are harmed and which are not. The itemization or disaggregating this requires is argued by many to require a slicing up of nature which is impossible; you cannot piece by piece unravel the threads of which nature’s network is composed (O’Neill et al. 2008).

Methodological Approaches: Principalist, Virtue/Care, and Pluralist Value Approaches

Next to this substantive grouping of approaches, a more methodological division is possible between fundamental or principalist positions, value- and experience-oriented positions, and pragmatist positions. In the first approach, the idea is that ethics should begin with identifying and justifying fundamental principles and obligations that can rightly claim universal respect and agreement. On the basis of these principles, people can then try to tackle more practical problems by applying them to local circumstances. The ideal principles function more or less as foundations but also as searchlights that assist in identifying the main bones of contentions. Utilitarians like Peter Singer (1975) and deontologists like Regan (1983) argue in this way. Regan, for example, argues for not interfering with animals on the basis of the principle of animal integrity. The principalist approach is helpful in delineating lots of possibilities but does not assist in procedural questions of discussing them, such as the selection of urgent topics, the procedure, and the type of information needed; moreover, it leaves out virtue ethics and long-term processes.

The value-oriented approach, like the first two, is a top-down approach, starting with the right values and then delineating what a valuable agriculture could be (Sandler 2007). A kind of ideal picture is sketched, and concrete reality is measured according to that. However, there are other approaches that start with human experiences. Eco-phenomenology, based on phenomenology, studies the nature of humans’ and animals’ first-person experiences, which include moral feelings of the environment and behaviors with respect to it. Abrams (2010) delineates a primordial space of relationality in which beings become experiencing humans and animals. Environmental hermeneutics emphasizes the importance of narratives and stories that people tell (O’Neill et al. 2008). In the case of Hulme (2009), this line of thought is unpacked considering mass and social media myths.

Another approach is the pluralist and democratic approach. This one starts with the practices in which people are involved and tries to find their

standards of excellence and their aims, and on the basis of these values and norms, it searches for problems, inconsistencies, and failures and then develops improvements (O'Neill 2008; Keulartz et al. 2004; see also “► [Environmental and Animal Pragmatism](#)”). Although the other approaches can be used as searchlights in these processes, they are not used as principles. In the case of animals, it means that the a priori abolitionist position of, for instance, Regan is rejected and one looks instead to practices in which human-animal relationships can flourish and that one tries to expand these: not leaving animals alone but living with them (Donaldson and Kymlicka 2011; Harroway 2008). This approach has also a clear connection with the capabilities approach of Sen (2010), who stresses that the concept of justice can be given shape step by step in comparing different practices that promote the flourishing of the capabilities of people and nature.

The Task of Environmental Ethics

Environmental ethics has a difficult task: it not only requires the application of ethical principles, but it also requires extensive analysis in which technical details are to be taken seriously. During this process, cherished notions of fundamental, non-applied branches of philosophy, such as the radical distinction between humans and animals or between culture and nature, can turn out to be insufficient.

The main tasks of environmental ethics are, first, to give a coherent overview of all the ethical problems people are confronted when dealing with environmental problems, such as pollution, habitat destruction, biodiversity loss, and climate change, and the preservation and conservation or construction of ecosystems. Therefore, environmental ethics is very much a collaborative endeavor with the environmental sciences, but it tries to do more than these particular disciplines in that it tries to unify all of different aspects of the problems and different levels of analysis. Second, environmental ethics explicates, analyzes, and evaluates the most relevant and important ethical issues. Again, it does this together with other disciplines, but it also maintains close contact

with stakeholders, and so it can contribute to acceptable solutions. Third, environmental ethics can delve deeper by proposing and explicating ethical principles, norms, values, and meanings that are important in dealing with environment; analyzing cases is very helpful here. Finally, environmental ethics can contribute to the question of how to study the environment and so can help to improve the environmental sciences. Finally, “environment” is an essentially contested item, thoroughly impregnated with values and ethical questions. It cannot be studied in a neutral way, and ethics can help in analyzing its meaning.

Just like in any other philosophical discipline, nothing is outside debate and unquestionable: controversies abound. However, within the arena of environmental ethics, there is one value that seems to be a fundamental assumption: the environment is an essential context for and element of human life. Many environmental ethicists want to argue for more than this and believe that the environment has an independent meaning which cannot be neglected. The environment covers relationships that one cannot annihilate; they require maintenance, exercise, and cultivation. When humans distance themselves too much from environmental relations, for example, when important elements of the environment are made of plastic or are only available through two-dimensional electronic screens, they are degrading these relations and themselves.

Because humans always have multiple bodily and material meaning experiences of their environment, humans have to exercise the capacities that allow them to have these as much as possible in balance with other important capacities. As a matter of fact, these meanings are always culturally and socially differently shaped, but humans have to continuously learn to deal with those differences and to be sensitive to the relevant environmental problems and overlapping concerns. The bodily aspect of our relation to environment also implies that a sense of place, even in a mobile society, is important in connecting with landscapes and with the people one trusts. This anthropological insight could contribute to a better relationship with the environment: less spoilage, less waste, and less neglect.

Environmental Ethics and Politics

The rise of environmental ethics was accompanied by activism, by writing, by organization of sit-ins and boycotts, by initiating local conservation areas, by participating in social media, and by political action. The relation between environmental ethics and politics can be diverse and can be directed toward governments, farmers, corporations, and supermarkets. Moreover, these kinds of activism manifest themselves in the supermarket by urging for more and relevant information on the ecological footprint of products, where they come from, how they are made, and which ethical decisions are made in their production process. Political action can be so strong that governments are compelled to issue strict regulations or better oversight of existing regulations; some companies are playing a key role and business can in some cases be seen as a “green avant-garde.” Many citizens find it frustrating that environmental problems and solutions are not always a priority for political parties and so exercise their agency via traditional media, new social media, or directly via the civil society groups.

Therefore, many ethical consumers become members of NGOs and other organizations when they want to contribute to “other regarding” political and ethical action. They contribute to these joint actions, although it is often not in their direct own interest, but in the interest of others, often people abroad. Environmental ethical activism is therefore more than citizen action, because it often transcends the borders of the nation-states to many areas in the world, like rainforests, tiger parks, and river deltas. Many activists act out a new kind of obligation, and in particular in acting together, they develop a first-person plural perspective of a group that act “vicariously” as advocates of silenced groups like next generations or nearly extinct animals.

For ethicists engaged in controversial issues such as animal welfare or environmental degradation, it is not always easy to meet norms of scholarly integrity and to take the relevant aspects fairly into account. Pure neutrality in this field is impossible; however, the rules and values of good scholarship are clear for many, and upholding them can

have a purifying and ideas generating effect. One of these values is the concrete engagement with practitioners and nature managers; here one learns what concrete problems arise in dealing with a certain ecosystem in which people have lived for a very long time. One learns to understand that these people often care very much about their surroundings and that environmental fundamentalism, which under all circumstances puts the environment first and gives the people living in it only an insignificant role, is a serious mistake.

Ethics and Environmental Sciences

The relationship between ethics and the environmental sciences is often described as a kind of norm-fact relation: the sciences deliver the facts and ethics develops principles and norms to act upon. Often, the deliverers of the facts, the scientists, are attributed also normative tasks in dealing with humans’ distorted relations with the earth (see “► [Ecotopia](#)”). Lewis Mumford writes “One of the major tasks of the twentieth century is the resettlement of the planet. The past three centuries have been centuries of random exploration . . . spontaneous and guided by insufficient knowledge; and much of the work of settlements to be done over again . . . Population that spread with no more social direction than the surface tension which gives definition to an ink blot, must be re-grouped and nucleated in a fashion that will make possible a co-operative, civilized life. Industries . . . must now flow out into new centres . . . conscious scientific intelligence must determine the new loci of industrial advantage” (Mumford 1940, p. 388; Keulartz 1998). However, these scientific proposals run several severe risks. First, the environmental sciences (like any science) suffer from controversies, and it requires normative assumptions to choose one party; second, societal processes have a logic of their own and cannot change just because scientists say that they should. Moreover, environmental sciences incorporate values and normative assumptions that steer their research. So, there are perspectives that try to have a more critical and distanced relationship with the sciences and to look for a

broad spectrum of inspiration, like social movements and various neglected social practices.

Outlook: Future of Environmental Ethics

One assumption of the environmental ethics of the eighties and nineties of the last century (in particular deep ecology, Naess 1989) was that the environmentalists of the West should have very strong opinions about the “wild” ecosystems in the South: they have to be preserved, and poor people that live in these areas are harming nature and should give way to, for example, nearly extinct species like tigers. It turns out that the opposite is true: poor people are much more dependent on regular ecosystem services, and as the Indian social ecologist Ramachandra Guha (1994) argues, environmental and human justice need to be brought in balance (see also “► [Environmental Justice and Food](#)”). The future of environmental ethics lies in a careful integration of global and local orientations, of natural and human values, and requires respecting the diversity of nature and humans and a sustainable form of agriculture. In particular, in Asia the challenges, especially those posed by climate change, are enormous and will require integrating population growth, increasing welfare, and growing demand for animal proteins on the one hand and nature conservation of huge areas with incredible ecosystems on the other. The Asian religious traditions, just like other movements, can be an inspiration. Finally, the stalemate between an environmentalism – which focuses on wild nature – and agriculture, which focuses on the expression of a so-called anthropocentric, dominating attitude, needs to be expanded to include more sophisticated approaches that consider the need of all humans to live well with food and nature.

Summary

Non-anthropocentrism is one of the main starting points in environmental ethics, and it implies that the moral domain covers not only humans but also animals and, depending on one’s outlook, species,

ecosystems, and the land. According to trans-generational ethics, even future generations are considered to be moral objects, which raises the issue of balancing current generational interests with those of the future. Utilitarian and deontological perspectives will give different answers to these questions, as will egalitarian and hierarchical approaches. An important issue is what to do with endangered species and biodiversity protection. According to ecocentric ethics, the land requires priority vis-à-vis animal ethics. A recent and growing challenge is the relationship between climate change and global justice. From a methodological perspective, one can distinguish between principalist, virtue/care, and pluralist value approaches. The tasks of environmental ethics were discussed as well as the relationships between environmental ethics, politics, and the environmental sciences.

Introduction

Environmental justice, understood here as a call for stronger consideration of social justice in environmental policy, is receiving increasing attention in policy, politics, and academic research. With social justice understood as concerns of fairness and equity as they are experienced within and between societies, environmental justice advocates make claims relating to the ways in which features of the environment, both positive and negative, are experienced differently depending on demographic factors such as ethnicity, gender, and income. Food – an essential environmental resource, intimately bound up with our health, practices, and cultures and stemming from increasingly globalized and industrialized production systems – is an issue that should be at the heart of these calls.

In mapping out the food dimension of environmental justice, this entry explores four particular ways in which the consumption and production of food have implications for justice. The first is the accessibility of food, which is quite distinct from other consumer products and has wide-ranging implications for health and social inclusion. The second is climate change, a key *intergenerational* and *intragenerational* justice issue. Agriculture and food processing and distribution not only contribute to climate change, they are also likely to be affected as its impacts are experienced. The third is the perception of injustice in global supply chains, with palm oil as a specific example.

Finally, the relationship between diet and justice to nonhuman nature is considered.

Environmental Justice

The environmental justice movement is generally understood to have originated in North America in the 1970s, with roots in the civil rights and anti-toxics movements. Protests about the location of toxic disposal sites raised concerns about disproportionate impacts upon demographic groups, particularly in terms of race and ethnicity. Agyeman recounts a clash of ideology between environmental justice campaigners and the established environmental movement. He argues that the former can be seen to represent a “grass-roots (re)definition of environmental issues, not (only) as wildlife, recreational or resource issues, but as issues of justice, equity and rights” (Agyeman 2000, p. 36). It can be seen, therefore, as a social justice challenge to the environmental movement. The concept and movement have expanded to bring environmental justice dimensions to campaigns on farmworker rights, incinerators, lead poisoning, and transportation, to name a few.

Gottlieb and Joshi build on the common notion that environmental justice is about recognizing the environment as “where we live, work, and play,” to introduce food justice as “where, what, and how we eat” (Gottlieb and Joshi 2010, p. 5). It is, they continue, about “ensuring that the benefits and risks of where, what, and how food is grown and produced, transported and distributed, and accessed and eaten are shared fairly” (2010, p. 6). Food democracy builds on another central tenet of environmental justice, that of procedural justice, in which fair and inclusive procedures are in place to address injustices and eliminate negative environmental impacts at their source (Agyeman 2003).

As the notion has spread around the globe, so have a multiplicity of conceptualizations. While the first decades of environmental justice campaigning saw a focus on the ways in which race and ethnicity affected environmental burdens, recent research has focused on injustices

experienced due to age, gender, indigenous status, disability, and income. The scope has broadened from a focus on “environmental bads” to one that also encompasses “goods,” such that it is concerned not only with protecting people from the effects of pollution but also with providing access to environmental resources, such as transportation and green space. Agyeman has posited “just sustainability” as a concept that brings together environmental justice with more conventional environmental campaigns toward a “sustainable society, locally, nationally and internationally, both within and between generations and between species” (Agyeman 2003, p. 323). While we should recognize that not all efforts to minimize environmental impact will maximize social justice and vice versa, just sustainability can be read as a call to find common ground between these agendas.

In the UK, there has been no direct equivalent of the environmental movement in the North America. It can be seen as an emergent policy principle rather than a direct focus of grassroots anger (Agyeman 2000), and there has been a focus much more on income than on race and ethnicity. In contrast to the grassroots origins of environmental justice in North America, work on the issue in the UK was initiated by established environmental NGO Friends of the Earth (Walker 2012, p. 25) and by the Environment Agency’s establishment of a program to look at “environmental inequalities.”

The environmental justice movement in South Africa drew many parallels with the USA, making connections between the civil rights movement and anti-apartheid struggles, sharing a focus on toxic and polluting activities, and making deliberate contrasts between these concerns and more traditional colonial and postcolonial ideologies relating to wilderness and nature conservation (Walker 2012). In Central and Eastern Europe, the “Transatlantic Initiative on Environmental Justice” networked with US contacts to work on regional issues, with a focus on the discrimination against Roma.

Although these are examples of self-identified environmental justice activity, it is also evident that environmental campaigners around the world

have increasingly taken on board justice concerns. Palm oil and climate change, discussed below, are just two examples of this. In discussing environmental justice, then, we need not be limited to those movements and organizations that refer to their work as environmental justice, but be open to broader discourses in which concerns about fairness and the distribution of impacts on people have influenced thinking on issues of environment and sustainability.

Access to Food

A well-established food justice issue is the accessibility of food to disadvantaged populations. This can be observed not only at a global scale but also within societies in the Global North. In an increasingly urbanized society, our food is generally produced, processed, and packaged as part of a globalized supply chain, with attendant impacts around the world. In this sense, it is like any consumer product. Yet food presents a special challenge, not least because it is a physiological requirement and one that we need to consume often: at its most basic level, it is not substitutable. In comparison to shortages of other consumer goods, lack of access to food provokes a very strong sense of injustice. Our diet has a profound impact upon our mental and physical well-being: it is not simply the bare provision of food that should concern environmental justice, but access to a healthy, culturally appropriate diet.

One aspect of access to food is affordability. A report by Friends of the Earth as part of the ESRC Global Environmental Change Programme (Stephens et al. 2001) found that around 20% of the UK population had difficulty affording healthy food, especially where other costs such as fuel and rent take priority. Food insecurity in developed countries has been linked to a prevalence of obesity, diabetes, anxiety and depression, loss of dignity and to lower educational attainment and behavioral issues in children (Burns et al. 2010, p. 2). In the Marmot review of health inequalities and the social determinants of health, food and diet were recognized as part of a group of health issues with “persistent and complex causes and relationships

[which are] multi-faceted, between, for instance, early years, education, employment, living environment, income and health” (Marmot et al. 2010).

Another aspect is the availability of healthy food and the provision of affordable, adequate transport to reach shopping facilities (Social Inclusion Unit 2003). A study into accessibility in the West Midlands town of Sandwell found that many residents had no fresh food within 500 m of their homes – which is the distance a healthy person is considered able to walk in 10–15 min – whereas the food that was available locally comprised predominantly high fat, high salt, cheap, and easily storable foods (Steel 2013). Numerous studies of cities in the USA have identified links between limited or no fresh food access and health-related disparities associated with race, ethnicity, and income (Gottlieb and Joshi 2010), and, as discussed, this “grocery gap” can be linked to a “transportation gap.” “Food deserts” has become a popular description of such situations and illustrates the complex relationship between local environments and diet.

As an issue of justice, however, food accessibility is concerned with more than just physical and financial access to basic foodstuffs. Food is bound up in our social and cultural lives, and what it means to “eat well” varies from culture to culture and person to person. Food demands competencies from the consumer: we need knowledge and skills to plan our diets and to select, store, and prepare meals, and these competencies can mean the difference between a healthy relationship with food and an unhealthy one. Understandably, then, projects such as the Bentley Bulk local food initiative (Sherriff 2009), Growing Manchester, and Incredible Edible Todmorden all incorporate elements of education and awareness raising.

Such an understanding demands a nuanced conceptualization of food security: Burns et al. (2010, p. 2) attempt to do this, for example, with “all community residents obtain a safe, culturally acceptable, nutritionally adequate diet through a sustainable food system that maximises self-reliance and social justice.” It has also been argued that discourses and practices relating to “alternative foods” may be specific to particular cultural contexts or ethnic groups through the

ways in which they are constructed and understood. Guthman et al. argue, for example, that “many of the discourses of alternative food hail a white subject and thereby code the practices and spaces of alternative food as white” (2011, p. 264). It is important, therefore, that inclusivity and cultural appropriateness are taken into account when creating projects and systems designed to improve accessibility, an example of justice as recognition and inclusion.

The temporal dimension of food consumption is also distinctive: we consume food often and make choices about it daily. In comparison with other consumer purchases, such as televisions or cars, food is subject to an ongoing series of daily and weekly choices and, although this means that there are in theory opportunities for rapid changes in diets, these must be understood within the context of enduring habits and social and cultural meanings. That is, food consumption must be understood as more than a series of individual choices: it is an ongoing relationship. An improvement in food accessibility, therefore, is more likely to result from ongoing sustainable practices and systems that engage with cultures and communities, rather than simple, one-off interventions.

One way to improve food access is to promote local growing projects at the individual, household, or community level. The availability of green spaces therefore becomes an issue. Green spaces have been identified as promoting other benefits as well, including improving air quality reducing flooding, and raising overall neighborhood quality (Walker 2012) and can thus be considered an environmental good. Involvement in food growing has been recognized as bringing numerous benefits beyond the direct contribution of food availability, including opportunities for social interaction, physical exercise, and skills development. Germany’s Interkulturelle Gärten, for example, are aimed at helping integration into a “migration society” by bringing together people from a variety of backgrounds with food and outdoor activity as a focus (<http://www.stiftung-interkultur.de/>). This is an example of an approach to environmental justice that encompasses both the cultivation of environmental goods and the minimization of environmental bads.

Climate Change

Food production, consumption, and distribution both affect and are affected by one of most pressing and wide-ranging international justice issues: climate change. This is the change experienced in climate as a result of rising global mean temperatures due to an accentuation of the naturally occurring greenhouse effect, a process commonly referred to as global warming. “With climate change,” argues Walker (2012, p. 179), “we are confronted with evidence of patterns of inequality and claims of environmental justice that span the globe, that permeate daily life and which pose threats to the current and future health and well-being of some of the poorest and most vulnerable people around the world.” EU food consumption accounts for 31% of all consumption-related greenhouse gas emissions, while in the UK the figure is estimated at 19% (Sustainable Development Commission 2008). It is a prime example of *intergenerational* (in)justice, since current emissions cause climate change impacts in coming decades. It is also a case of *intragenerational* (in)justice since, while the greatest proportion of the greenhouse gas emissions come from the Global North, that is, the richest, most economically developed countries, it is well established that the Global South – the poorest, least economically developed countries – will bear the brunt of the impacts (Walker 2012).

A further dimension of justice in the relationship between food and climate change is the vulnerability of agriculture to changes in climate. Climate scientists are not able to predict exactly what impacts will occur, but they could carry a high risk of causing major damage. Policy makers must therefore take into account both uncertainty and risk. The emerging consensus is that higher-latitude regions such as North America and Northern Europe may benefit from longer periods of warm weather that may increase yields, but water shortages may constrain production. On the other hand, in the low-latitude regions such as Africa, parts of Asia, South America, and Australasia, the negative impacts are already being seen (Garnett 2008). Extreme weather could affect transport and storage infrastructure, and fertilizer plants and

manufacturing sites, and could put the rural poor, who rely in a direct way on getting to market to both buy and sell, in a particularly vulnerable position. Moreover, such fluctuations could threaten the security of the world food supply and bring increased volatility to food prices, again affecting poor consumers the most. The world's poorest and most vulnerable will be hardest hit by climate change, and this applies at the global scale as well as within countries in the Global North (Marmot et al. 2010, see pp. 77–78, 127–129).

(In)Justice in the Supply Chain

Transnational agricultural corporations control 40% of world food trade, with 20 companies controlling trade in coffee, six controlling 70% of wheat trade, and one controlling 98% of packaged tea (Patel 2013). One justice dimension of food is the concern about the impact of industrialized and globalized agriculture and associated industries.

Protests within the global neoliberal economy can be seen as “a call for recognition and preservation of diverse cultures, identities, economies and ways of knowing” (Schlosberg 2004, p. 524). People's movements exist with the aim of “conserving livestock diversity and protecting the basis of sustainable agriculture” as a reaction to the pressure to produce meat for export (Shiva 1999, p. 59). In Brazil alone, the equivalent of 5.6 million acres of land is used to grow soya beans for consumption by farm animals in Europe (Lang and Heasman 2004). These “ghost acres” not only illustrate the inefficiency of much agriculture but also highlight equity concerns: land used to grow food for export becomes unavailable to the poor to grow staples to meet basic needs. This process fuels displacement to urban areas, adding to overcrowding and creating new challenges of feeding rapidly urbanizing populations. Between 1979 and 1999, when Kenya almost doubled the proportion of its vegetables being grown for export, vegetable consumption in the country decreased by 39% (Jones 2001, p. 52).

An example of these global impacts through the corporate food regime is the “palm oil

industrial complex” (Pye 2010, p. 854). The non-profit, industry-led Roundtable on Sustainable Palm Oil has been created to promote the production and use of sustainable palm oil (Laurance et al. 2010), following concerns about the ecological and humanitarian impacts of palm oil's rapid spread across tropical regions, especially Malaysia and Indonesia. Alongside palm oil's use across the food chain, a driver for its development in global markets has been the push for biodiesel in the EU's transport targets: a fuel once seen to be sustainable but now associated with rainforest destruction and food crisis (Pye 2010). Environmental justice campaigners allied themselves with indigenous peoples, whose lifestyles, such as farming smallholdings, were seen as exemplars of sustainable resource management. International NGOs such as Friends of the Earth and Greenpeace have campaigned on this issue, not only from the angle of more conventional environmental concerns, such as deforestation and the plight of the orangutan, but also from the point of view of the displacement of, and health impacts experienced by, the indigenous peoples. There have been numerous protests by the “independent peasantry,” and some village-led struggles have been successful in preventing the imposition of plantations (Pye 2010).

The New Economics Foundation is one of the organizations raising concerns about the dominance of supermarkets and drawing connections with justice issues in the supply chain (Simms 2007). Campaigners argue that the supermarket business model, in its attempts to bring uniformity to products and cut costs, results in produce that does not fit high standards of cosmetic uniformity being wasted and therefore also the effort that went into growing it; workers being subject to low wages and cost-cutting hazardous conditions; and environmental resources, not least land and water in the Global South, being used for export products and luxury horticulture items rather than for the production of produce that local people can access and afford. While supermarkets have programs to improve supply chain standards, campaigners argue that they are “freshening the dragon's breath” (Simms 2007, p. 282) rather than making fundamental change. Well-known standards such as Fair Trade offer a way to try to ensure

higher standards and fairer reimbursement for producers, but some argue that this does not bring fundamental change but is “a way for farmers, hanging on by their fingernails, to be able to hang on a little longer” (Patel 2013, p. 317). It is argued, for example, that underrepresentation of farmers on the certification bodies, in comparison to that of distributors and retailers, means prices are still relatively low and pressure to grow monocultures continues. The point is not to dismiss the role of supermarkets and efforts to improve trading standards and working conditions, but rather to show that these have been subject to claims of (in)justice.

Justice to Nonhuman Nature

While the environmental justice discourse is predominantly concerned with injustices to people, there is a school of thought that nature itself should be considered a subject of justice. Given the role of animals and ecosystems in food, this is of interest in this entry. That is, parts of nature should be treated as moral subjects because they have worth beyond their value to humans. While statements about the rights of nature, and its intrinsic value, are rhetorically impressive, they are viewed by some as ontologically and practically problematic, although it could of course be argued that this is the case for all attempts to ground rights, including human rights.

The notion of environmental pragmatism can be considered an alternative to the attribution of intrinsic value to nature. It holds that there is nothing upon which intrinsic value can be placed that does not also have some extrinsic value. For example, the protection of rainforests could be argued on grounds of their intrinsic value, for their own sake, but the same argument could be made on less controversial grounds by appealing to the extrinsic value of their contribution to the climate that supports human life, the habitat it provides for humans, or the pleasure individuals have from knowing that rainforests exist. Some therefore argue that an “injustice” to a part of nature can be (more usefully) understood as an injustice to those people who benefit from it, and this certainly

makes the concept more workable in the context of current environmental justice discourse.

Another way to understand the impact of food production on ecosystems is through considering the impact upon individual animals and species: while, a rainforest may seem a rather nebulous moral subject, justice to animals may be a more workable conceptualization. Spreading monocultural production, for example, has an impact on biodiversity and this can threaten the habits of wild animals. The use of pesticides and fertilizers in agriculture can also have a detrimental effect on wildlife. In April 2013, for example, the EU banned some widely used pesticides out of concern for bee health and the value of their pollination services. In some cases, endangered species are hunted for high-value food products: bluefin tuna, the Chinese giant salamander, and green sea turtles are examples, as are lions and tigers. In some instances, however, there is a complex relationship between human rights and the preservation of a species, as is the case with whale hunting by the Inuit in the polar regions of North America. In such instances, there is a need to address the competing values of nature and humanity.

An issue that has direct resonance with justice and nonhuman nature is the role of animals in agriculture and in our diets. Philosopher Peter Singer, seen as the founder of the modern “animal rights” movement, has argued that we have responsibilities in terms of the ways we treat other species, concluding that we should not be using them for food. He argued that animals are moral subjects because they are sentient and feel pain. As well as concerns for animal welfare, the thinking behind vegetarian and vegan diets reflects concerns about the environmental impact and inefficiency of meat production, particularly in its intensive forms such as factory farming (FOA 2006); the global justice implications of the spread of soy and palm oil to produce animal feed; the health implications of diets high in meat; and the welfare of animals in agriculture, particularly intensive farming. While some argue for the wholesale removal of animals in agriculture, others see some uses as beneficial, particularly in more traditional production systems in which they can provide fertility, traction, and useful by-products.

Summary

Environmental justice has developed from its roots in the 1970s in North America to a movement, policy perspective, and area of research that have international reach and geographical differentiation in their application and conceptualization. Food production and consumption, which is intimately related to human health and environmental quality, is an important area of environmental justice. One dimension is the accessibility of food, an exploration of which has revealed the importance of understanding not only physical accessibility but also the competencies people have in dealing with food and the ways in which food is bound up in our social and cultural worlds. Another is climate change, which is a prime example of *intergenerational* and *intragenerational* justice. There are concerns about the injustices experienced by those working in the global supply chain or displaced to make way for its spread. Finally, while environmental justice has been primarily concerned with justice to human communities, it can be argued that elements of nature, can also be brought within an environmental justice frame and that this has implications for the role of animals in agriculture.

Introduction

The briefest definition of Epicureanism is hedonistic materialism. However, this technical description

is potentially misleading to those unfamiliar with philosophical terminology. Similarly, the terms “epicure” and “epicurean” are now commonly associated with luxurious or *recherché* appetites and even vulgar excesses, although the Hellenistic Greek philosopher Epicurus (341–271 BC) encouraged moderation and a simple diet. It is true that he advocated pleasure (*hēdonē*) as a criterion of ethical choice, but his ethics must be understood within the context of his physics. To understand what Epicurus taught about food and pleasure, or even what he meant by pleasure, one must turn to the ancient sources.

The first vulgar yet comedic caricatures of Epicureanism emerged in antiquity, deceptive but memorable distortions of the teachings of Epicurus. Philosophical opponents from his own day including his own disaffected students, later Roman and Greek authors including Cicero and Plutarch, early Church Fathers, and medieval sources misrepresented and distorted Epicurus and Epicureanism to such an extent that their caricatures have persisted in common use today. However, the positive influence of Epicureanism on Renaissance, Enlightenment, and Romantic thinkers and on modern intellectuals and writers demonstrates the indestructible longevity of and persistent ideological resistance to this Hellenistic school of thought.

Basic Description of Epicureanism

According to Epicurus, human happiness is possible only through an understanding of the physical world and its unseen workings. Ignorance of one’s surroundings and of the composition of the universe leads to irrational and superstitious pre-occupations, such as fear of death and dread of the gods. Epicurus sought to rid mankind of these worries through an explanation of theoretical physics based on the atomism of Leucippus and Democritus. Through careful study of the workings of the universe and the knowledge that everything consists of atoms and void, man is able to achieve peace of mind (*ataraxia*), an inner calm and sense of equilibrium, which is the highest pleasure, the greatest goal in life. Epicurus also

encourages a careful discrimination among pleasures, rejecting pleasures that are momentarily intense but followed by pain. He argues for moderation, the pleasure obtained by the self-sufficiency of living a simple life, the joys of friendship, and even the withdrawal from an active political career, as summed up in the maxim, *lathe biōsas* (“live unnoticed”).

The philosophy of Epicurus demonstrates a keen awareness of, engagement with, and frequently polemical responses to the works of his philosophical predecessors and contemporaries. Although clearly in debt to the earlier work of the atomists, Leucippus and Democritus, and the hedonism of Aristippus, Epicurus nonetheless criticizes their work as insufficient. He attacks other philosophers on whom his own work rests, including Plato and Aristotle, and his former teachers, reserving particular contempt and vitriol for Nausiphanes, an atomist with skeptical inclinations, who clearly had a formative influence on Epicurus. However, Epicurus did not allow criticism of himself from his followers. An oath of obedience to Epicurus and strict adherence to his teachings were required of members of Epicurean communities. Some of the most vicious comments about Epicurus and his philosophy come from his contemporary and former student, Timocrates, who, upon leaving the school, wrote a book called *Pleasant Things*, in which he accuses Epicurus of profound ignorance of philosophy and disgusting habits, including cohabiting with numerous women (perhaps a criticism of Epicurus’ inclusion of women as full members of his school), spending an immoderate amount of money on food, and vomiting twice a day because of his luxurious living. Diogenes Laertius mentions these criticisms in his biography of Epicurus but discounts them as calumny.

Sources

Although Epicurus was a prolific author of over 300 works, few survive in their entirety or at all.

What little is known of his life is found in the tenth chapter of Diogenes Laertius’ *Lives of the Eminent Philosophers*, written in the second

century AD. Diogenes’ biography also preserves the text of the three complete letters of Epicurus (the *Letter to Herodotus*, the *Letter to Pythocles*, and the *Letter to Menoeceus*) and a collection of quotations known as the *Principal Doctrines*. A fourteenth-century Vatican manuscript preserves a similar collection of quotations, the *Vatican Sayings*.

Among the primary sources for Epicurean philosophy are the fragments of an inscription from Oenoanda, in Lycia, modern southwest Turkey. In the second century AD, Diogenes of Oenoanda, an Epicurean Greek, carved a summary of Epicurus’ philosophy onto the wall of a portico in his hometown. The inscription provided Diogenes’ synopsis of Epicurus’ teachings on physics, epistemology, and ethics. The three registers of the inscription contained three treatises, on old age, on physics, and on ethics. Less than a third of the inscription, an important source, has been recovered.

Charred papyrus fragments of Epicurus’ 37-volume treatise *On Nature* and the works of authors who quote him were found in the eighteenth century in the personal library of the Epicurean philosopher and poet, Philodemus, at Herculaneum. Some 1500 papyrus scrolls were semi-preserved at the Villa of the Papyri when the city was buried by volcanic ash during the eruption of Vesuvius in AD 79. Because of the extremely fragile condition of the recovered papyri, it was not until the mid-1980s that researchers were able to develop an effective technique for reconstructing and reading the fragmentary documents. Today, a UCLA-led international team of scholars, the Philodemus Project, works to reconstruct, translate, and publish the texts. Philodemus (ca. 110 BC–ca. 35 BC) was a member of the literary elite, who counted the Roman poet Virgil (70 BC–19 BC), possibly Lucretius (ca. 99 BC–ca. 55 BC), and Horace (65 BC–8 BC), among his many students. Philodemus’ circle was an important point of entry for the ideas of Epicureanism and other Hellenistic philosophies into the Roman world and Latin literature.

Numerous quotations, fragments, and testimonies on Epicurus found in Greek and Roman

literary sources are collected in Usener's (1887) compilation, *Epicurea*.

However, the most important extant source for Epicurean philosophy is Lucretius' hexameter poem, *De Rerum Natura* (*On the Nature of the Universe*), the title itself a translation of Epicurus' Greek *Peri Phuseōs* (*On Nature*). Lucretius' work is best understood as a lengthy exposition of Epicurean philosophy, addressed to his patron, the Roman aristocrat and politician, Gaius Memmius. Lucretius describes the poetic form of the treatise as "honey on the cup of wormwood" (a phrase perhaps better understood as "a spoonful of sugar helps the medicine go down") as it is calculated to make the work's technical content more pleasurable and palatable to its reader. Lucretius' poem is dominated by the Epicurean desire to free mankind from superstition and fear of death. Death is nothing more than the dispersion of atoms, which make up the human soul. Although the gods exist, they are unconcerned with human affairs and need not be feared. For if they concerned themselves with mortals, they would be troubled, and gods in their blessedness, by definition, cannot be troubled. Rather, their tranquility provides the ideal for Epicurean peace of mind, which each member of the sect should strive to emulate.

A brief summary of Lucretius' poem will show which aspects of Epicureanism he chose to elaborate. Book I is devoted to an explanation of atoms and the void (space necessary for the movement of atoms) and an attempt to refute the physical systems presented by the pre-Socratics Heraclitus, Empedocles, and Anaxagoras. Book II presents the kinetics of atomic theory, with particular emphasis on the properties and movement of the atom. Book III discusses the material composition of the human soul and develops various arguments for its finite existence. Book IV contains Epicurean theories of sense perception, psychology, and will, concluding with a disillusioned description of love and sex. Book V discusses the origins of the world, astronomical phenomena, the origin and development of the human species, and the growth of human institutions, language, art, and religion. Book VI, loosely organized, explains various natural phenomena, including thunder, lightning, the periodic

rising of the Nile, the attraction exercised by magnets, etc. It concludes rather abruptly with a description of the plague at Athens at the beginning of the Peloponnesian War.

Although Lucretius is faithful to the teachings of Epicurus, his primary focus is on Epicurean physical theory. There are, however, moments in the poem when Lucretius either highlights parts of the Epicurean system or depends upon methodologies or procedures that he does not explicitly set forth. These are the *Canonic* ("Rules of Investigation"), Epicurus' moral theory, and the beliefs about the gods and religion.

Insofar as the criteria of truth and moral theory are relevant to a discussion of food and pleasure in Epicurean thought, further discussion of these elements is necessary.

Epicurean Criteria of Truth

The fundamental criterion is sensation. All objects of perception are true and real, and the criteria of truth are sensations and concepts and feelings. Epicurus holds that while sensation is irrational, there is no other criterion by which one can test it. Sensation must be trusted as a reliable guide to the world, insofar as it is perceptible. Thought is derived from sensation. The perceptible world is an instructive guide for the investigation of imperceptible objects. Several images of any one class of things unite to form a general concept of a thing, to which we can refer as a test. This general concept of Epicurus is called "anticipation," because it allows one to anticipate or identify the appearance of anything one seeks or wishes to construct. The third criterion of truth is feeling (*pathos*), which is the basis of Epicurean moral theory. All sensations are accompanied by feeling, but feeling is the distinction between pleasure and pain.

Epicurus distinguished between two classes of objects of investigation: things perceptible in normal experience and things imperceptible. The latter category is subdivided into things that are perceptible but distant (not close at hand for investigation), such as celestial bodies, and things, which by their very nature are imperceptible, such as the atoms and the void.

Epicurean Ethics

Epicurus' *Letter to Menoeceus* is probably the best exposition of Epicurean moral theory. However, this theory is also evident in most of the *Principal Doctrines* and in many other quotations and references in other authors. It is not, however, featured prominently in *De Rerum Natura*. According to Epicurus, every sensation is accompanied by the feeling (*pathos*) of pleasure or pain. The end or purpose (*telos*) of action is pleasure; pleasure is good; pain is bad. Like sensation, feeling is immediate and irrational. It is also universal. All living creatures, as soon as they are born, take delight in pleasure but resist pain. For example, they desire the pleasure of not being hungry and not being thirsty. They do this by instinct, a natural impulse apart from reason. Not only is pleasure an immediate and irrational sensation but the processes of pleasure and pain are also atomic movements of dislocation and readjustment. Epicurean moral theory is firmly grounded in its physical system.

The assertion that it is man's purpose (*telos*) to seek pleasure ("the pleasure principle") led to popular misconceptions of Epicurean morality in antiquity and later. For example, in a hostile passage, Plutarch alleged that the Epicureans measure the amount of pleasures with compasses, from the stomach as center (Plut., *Non posse*, 1098D). However, this was not Epicurus' philosophy. He did not teach, as did the hedonist Aristippus and his followers, the Cyrenaics, that each successive moment should be filled with maximum pleasure. Epicurus comments in his *Letter to Menoeceus* that when he talks about pleasure as the goal of life, he is not talking about the pleasures of sensuality, but rather of freedom from pain and mental affliction. It is not eating, drinking, and sex but sober reasoning and the virtue of prudence that produce the happy life. The highest pleasure is thus associated with the absence of pain (*aponia*).

Three further considerations refine Epicurus' concept that pleasure should be sought and pain avoided. Some pleasures bring pain; some pains result in pleasure; therefore, not every pleasure should be chosen, nor every pain avoided.

Pleasure is the satisfaction of want. According to Epicurus, what the body desires is not to be hungry, not to be thirsty, and not to be cold. Such pains are caused by atomic dislocation, and thus, the process of readjustment brings pleasure, as does the equilibrium that results. The static or *katastemic* pleasure of equilibrium is greater and longer lasting than the pleasure of movement (*kinetic* pleasure). The Cyrenaics had been aware of the distinction between *katastemic* and *kinetic* pleasures but rejected it. For the Cyrenaics, *katastemic* pleasures were not pleasures at all but rather the experiences of a corpse.

Lucretius clearly describes this satisfaction of want with reference to eating and drinking. The taste and consumption of food and drink bring a certain kinetic pleasure, but it is in their satisfaction of the pains of hunger and thirst that they restore equilibrium to the body. Overindulgence in food or drink, while resulting in immediate kinetic pleasure, would disturb the equilibrium of the body and therefore should be avoided. It is always the *katastemic* equilibrium of satisfaction that should be sought over the kinetic pleasure of consumption. Cicero, himself a Stoic clearly engaged in polemic against the rival Epicurean school of thought, misrepresents Epicureanism by saying that the Stoics understand correctly that the first natural impulse of children and animals is for self-preservation, while the Epicureans hold that this first impulse is for kinetic pleasure. Rather, it is clear that Epicurus sees this first natural impulse as a desire for *katastemic* equilibrium, akin to a desire for self-preservation, as it depends on the satisfaction of basic needs. Epicurus would acknowledge that the kinetic pleasures of taste and consumption accompany the satisfaction of the pains of hunger and thirst, but it is incorrect to attribute to him the notion that the first natural impulse is solely for the thrills derived from these sensations.

Thirdly, there is a limit to pleasure as the satisfaction of desire, beyond which pleasure cannot be increased, but simply varied. Desires may be divided into three classes: physical and necessary, e.g., food, clothing, and shelter; physical but not necessary, e.g., sexual pleasures; and neither physical nor necessary, for example, elaborate

food or clothing. The first must be satisfied, the second should be limited by prudence, and the third should be rejected as unnecessary.

If one considers all these elements together, what emerges is that the maximum amount of pleasure is to be obtained from the simple life, which brings pleasures free from pain, results in the static pleasure of equilibrium, observes the limits of pleasure, satisfies those physical pleasures that are necessary, and wisely limits or rejects those that are unnecessary. This simple life is within the reach of everyone, as nature has made it easy for humankind to satisfy its most basic needs. What is not easy is unnecessary to satisfy.

There are pains of the body over which one does not have the same control as over one's basic needs, such as those due to disease or accident. If pain is acute, it does not last long, for it either kills or is cured. If pain is chronic, it is not severe and even permits a predominance of pleasure over pain. To obtain complete freedom from pain, one needs both the control of one's bodily desires and the gift of health.

The mind, too, has its special pleasures and pains. It shares the pleasures of the body, but it also has the capacity for memory and anticipation, which the body does not. The mind also has its own unnecessary desires, which may bring pain, such as avarice, and the desire for wealth, ambition, and public recognition, such as honors like crowns and statues. Desires for power and wealth often lead to crime; the possession of wealth and power seldom leads to the security of a tranquil life. Lucretius also discusses the pain associated with the mind's ability to look back, which gives rise to remorse or the pangs of a guilty conscience, together with fear of punishment. This is often associated, especially in religion, with the fear of death. These latter two great fears of the mind arise from its ability to look into the future. Both the fear of the intervention of the gods in this life and the fear of the punishment of the soul after death may be dissipated by study of Epicurus' physical theory.

Beyond the dissipation of fear, the mind's greatest positive pleasure is obtained through the study of philosophy, which Epicurus promotes as

appropriate and enjoyable during all stages of life. The joy of friendship is also encouraged, and the study of philosophy with a friend unites these two highest pleasures of the mind. Finally, to guard against all disturbance of the mind, the true philosopher will eschew public life and politics and live unnoticed (*lathe biōsas*).

Significance of Epicureanism/Conflation with Gourmandism

It should be clear from Epicurus' moral theory that he advocated a life of moderation and simple pleasures and that he taught that happiness is possible even when one experiences physical pain. Nonetheless, detractors often sought to distort and discredit Epicureanism for ideological purposes. Thus, maxims such as "men feast and drink because they know that pleasure is short-lived" (*De Rerum Natura* 3.913–15) are taken out of context and are understood, incorrectly, as a synopsis of Epicurean ethics. The hedonism of Aristippus and his followers is often wrongly attributed to Epicurus.

Epicureanism According to Early Church Fathers

Early Church Fathers such as Justin Martyr, Tertullian, Clement of Alexandria, Jerome, and Augustine, some quoting Cicero extensively, sought to discredit Epicureanism. They exaggerate the primacy of the "pleasure principle," viewing it as incompatible with the forms of asceticism popular in the early church. In addition, they saw Epicurus' teachings about divine indifference to human concerns or afflictions and the mortality of the soul as inimical to Christian thought, for Epicureans deny the immortality of the soul and invoke the study of philosophy and the workings of the physical universe to allay fears about death and the afterlife that are provoked by religious superstitions.

However, neither Epicurus nor Lucretius was an atheist, and both adduced arguments for the existence of the divine. Impiety, according to Epicurus' *Letter to Menoeceus*, is to accept popular opinions about the gods, which in fact

misrepresent them. Plutarch relates that Epicurus used to claim that although he destroyed providence, he left a place for piety (Plut. *adv. Colot.* 8.1111B). In Epicureanism this piety manifests itself in the contemplation of the world with an untroubled mind, which is in itself an act of worship. Since the tranquil life of the gods is the moral ideal, the imitation of their life is a form of worship. Epicurus saw in this tranquility a communion with the divine. In this way, “a blessing comes to men from the gods,” as Eusebius, an early Church Father noted (Euseb. *Praep. Ev.* 15.5).

Although the school of Epicurus at Athens was still open in the third century AD, when other schools had been closed, by the early fifth century, Augustine, a Neoplatonist, could declare that “their ashes [those of the Stoic and Epicurean schools] are not so warm as that a single spark can be struck out from them against the Christian faith” (Aug. *Ep. 118*, ch. 2). Augustine singles out Epicureanism as the school of thought most in conflict with the tenets of Christianity.

Middle Ages

As Epicurus’ teachings were considered the least adaptable to Christian theology, his works did not circulate in the medieval period as widely as those of other pagan writers, such as Plato and Aristotle. Nonetheless, Lucretius’ poem was available in ninth-century Germany and in France during the twelfth. Quotations of Lucretius appeared in the Latin grammars of Probus and Nonius Marcellus, in Isidore of Seville’s encyclopedic *Etymologies* (seventh century), and in Hrabanus Maurus’ *De Universo* (*On the Universe*, ninth century). However, apart from Lucretius’ poem, there is no systematic treatment of Epicurean philosophy in this period.

But during the Middle Ages, a double image of Epicurus emerges: on the one hand, Epicurus the philosopher, the proponent of an atomistic view of the universe, and, on the other, Epicurus the gatekeeper of the garden of earthly delights, playing the vulgar roles of cook, bartender, and pimp. (Cf. Martianus Capella’s *Marriage of Mercury and Philology* [fifth century], John of Salisbury’s *Policraticus* [1159], John Gower’s *Mirour de*

l’omme [1376–1379], and Chaucer’s *Canterbury Tales*.).

Christian polemic against Epicurus continues. Towards the end of the medieval period, Dante locates Epicurus in the Sixth Circle of his *Inferno* for denying the immortality of the soul.

Renaissance

Poggio Bracciolini’s discovery of a manuscript of Lucretius’ poem in a monastery near Lake Constance in 1417 aroused great excitement, but the first extended Humanist treatment of Epicureanism was Lorenzo Valla’s (1431) *De Voluptate* (*On Pleasure*), which was written without reference to Lucretius. Although Lucretius was readily available by the mid-fifteenth century, the general identification of Epicureanism with extreme hedonism was such as to discourage the orthodox from too open an interest in this philosophy. Nonetheless, Michel Montaigne’s *Essays* (1580) demonstrate a more than casual familiarity with Lucretius, containing no fewer than 149 quotations. François Rabelais’ *La vie de Gargantua et de Pantagruel*, five sequential novels written in the sixteenth century, are Renaissance tales based on medieval themes. Although Rabelais does not mention Lucretius or Epicurus by name, his novels clearly bear the impression of the bawdy medieval persona of Epicurus. The story is that of a long wish fulfillment in nearly all areas of mental and physical, although not sexual, desire.

Among the scientists of the Renaissance who sought to revive the theories of the workings of the universe espoused by Epicurus and Lucretius were Giordano Bruno (1548–1600) and Galileo Galilei (1564–1642). Both of these men suffered severe censure from the Catholic Church for these and their other ideas, considered heretical.

Afterwords

In the seventeenth century, the anti-Aristotelian philosopher and scientist Pierre Gassendi undertook a dramatic revision of Epicureanism to remove it of elements at variance with Christian teaching. Although Epicureanism was practically unrecognizable as a result, Gassendi’s efforts led to a dramatic upsurge in European scholars’ interest in the scientific theories of Epicureanism.

Influenced by Gassendi, John Locke's interest in Epicurean Canonic (the "Rules of Investigation") and in the primacy of sensation in the formation of ideas played an influential role in the development of British empiricism. Gassendi's counterpart in the English-speaking world was Dr. Walter Charleton, graduate of Magdalen Hall, now Hertford College, Oxford, and physician in ordinary to Charles I and Charles II and future fellow of the Royal Society and the Royal College of Physicians. Charleton's first publication, *The Darkness of Atheism Dispelled by the Light of Nature* (1652), advertised that it was the "new" atomism that he espoused. At about this time, a characterization of the Epicurean emerges that is closer to the modern connotation of "epicure," someone who cultivates refined and sophisticated tastes and manners at table. William Whately's *Protopypes* (1646) describes Potiphar as "such an epicure was [he] – to please his tooth and pamper his flesh with delicacies."

In nineteenth-century America, Thomas Jefferson identifies himself as an Epicurean in his 1819 *Letter to William Short* and provides therein an accurate précis of Epicurean philosophy. In England, the Epicurean promotion of happiness as the chief end of living provided support for the Utilitarian movement of Jeremy Bentham (1748–1832) and John Stuart Mill (1806–1873). Bentham was an ethical hedonist, and drawing upon Epicureanism, he held that the moral rightness or wrongness of an action was a function of the amount of pleasure or pain that it produced. He formulated an algorithm, the *hedonic calculus*, to facilitate selection of the best course of action by considering the variables of the intensity, duration, certainty, proximity, proliferation, purity, and extent of pleasure and pain associated with it. Bentham's student Mill correctly cites the primacy of intellectual over physical pleasures in Epicureanism, and Mill's "proof" of the principle of utility adduces the Epicurean reliability of sensation. According to Mill, just as visible objects can be seen and audible objects heard, so desirable objects are desired. Walter Pater's *Studies in the History of the Renaissance* (1873) and his philosophical novel *Marius the Epicurean* (1885) were important contributions to the Aesthetic and

Romantic movements. In the early twentieth century, the works of the French author and philosopher Anatole France (*The Garden of Epicurus* [1895] and *The Gods Are Athirst* [1912]) demonstrate sympathy with Lucretius' Epicureanism. In 1921 France won the Nobel Prize for Literature, and in 1922 the Catholic Church placed all of France's works on its Index of Prohibited Books.

Summary

The positive influence of Epicurean philosophy throughout the ages should not be underestimated. Simultaneously, the satiric caricatures of the vulgar gourmand and the fussy epicure yet persist. Nonetheless, these are incorrect characterizations of Epicurus' original philosophy.

Equipment Sharing in Agriculture

Machinery sharing; Shared use of farm assets

Introduction

For many farming operations, shared use of machinery may offer a “trifecta” for improving farm business performance – increased profitability through production efficiency and cost reduction, reduced risk, and a reduction in invested capital. Shared use of machinery, with or without joint ownership, is one strategy growers have explored to gain access to equipment that is used only infrequently and is relatively expensive, making individual ownership impractical or even infeasible. Access to new, technologically advanced farming equipment can directly affect the income statement through improved productivity and quality and replace expensive or hard-to-find labor. Higher capacity equipment than could otherwise be owned alone can reduce time windows needed to complete critical operations (e.g., planting or harvesting before the rains) significantly reducing production risk. In many cases, owning only a share of a high-priced machine reduces individual investment and the invested capital, increasing returns on assets and equity. However, the fact that shared use of machinery is relatively rare suggests that the costs involved in sharing outweigh the benefits for the vast majority of farmers.

Machinery sharing rings and other farm-level cooperative arrangements are more common in Europe and Canada. A report on the socioeconomic impacts of rural business rings in Scotland estimates that 23% of Scottish farmers belong to a machinery ring. De Toro and Hansson report 5000 members in 20 associations in Sweden noting this is only about one-fifth the level of activity in Germany (2004). Harris and Fulton (2000a) report more than 1000 member farms in 47 CUMA's (Coopérative d'Utilisation de Matériel Agricole – loosely translated as “cooperative for the use of farm implements”) in Quebec. In the United States, the practice of sharing equipment and labor with other producers on a more routine basis is less common, but there is some evidence that interest in the idea is growing. For example, the original idea behind the agricultural leasing firm MachineryLink was to share machinery between farmers over a geographic distance in

order to take advantage of differences in growing seasons across regions.

Potential Benefits of Equipment Sharing

Cooperative equipment and labor sharing arrangements cannot only permit small- and medium-sized producers to access cost-reducing technology and economies of scale without incurring significantly more debt or acquiring more land, they can also provide less obvious benefits. For example, management and marketing benefits for the operation and its participating producers may come as a by-product of the coordination required to make the cooperative work.

Working in a group to share machinery tends to increase the number of acres serviced by the machinery, reducing inputs and average costs, for a given amount of output. Sharing can therefore result in greater efficiency, making newer, larger, and more technologically advanced equipment economical. Capital costs decline as the number of partners increases for two reasons. First, self-financing becomes easier. Second, capital will be used more intensively and thus more efficiently. In addition, group members can in some cases improve labor productivity, making more efficient use of labor during peak fieldwork times, by coordinating tasks to reduce duplication and allowing for task specialization (Allen and Lueck 1998; Edwards 2009b). Such managerial improvements result in internal economies of scale or an ability to produce more output with the same inputs.

The coordination of farming activities related to equipment sharing may also result in external economies of scale, or size advantages enjoyed in accessing inputs, obtaining and negotiating terms of credit, storage, services, and marketing and distribution opportunities. For example, larger farms can often negotiate volume discounts on inputs. Larger farms may be able to attract specialty contracts that pay premiums for delivery of a larger amount of product. Like marketing cooperatives which obtain higher retail prices through quality assurance, smaller farmer groups may be able to successfully coordinate production

practices such as planting and harvest times, in order to maximize quality specifications.

Other benefits include an ability to draw on the experience, labor, and ideas of other members, lower financial risk, shared operational risk, and environmental benefits from reduced input use. Sharing equipment is also a strategy to help younger farmers get started in farming with lower upfront investment in machinery (Edwards 2009a, b; Samuelsson et al. 2008; Andersson et al. 2005; de Toro and Hansson 2004; Harris and Fulton 2000a, b; Gertler and Murphy 1987; Gertler 1981; Groger 1981).

Potential Costs of Equipment Sharing

Thus, the question arises: if there are so many potential advantages to sharing equipment with other growers, why is the practice so rare? Certainly, there are some apparent additional explicit costs from sharing equipment relative to individual ownership. Transportation costs of moving equipment among farms can be significant, particularly if sharing occurs over some distance. There may be costs incurred in setting up an agreement, for example, legal fees for designing contracts or establishing a formal business entity and in enforcing the agreements and settling disputes should the need arise. In addition, there are a number of more subtle potential costs involved in joint use of an asset like farm machinery. A number of pecuniary and nonpecuniary costs may be incurred by partners in a sharing arrangement as a result of the need to make collective decisions and the division of the benefits derived from the jointly owned or shared asset(s). Potential drawbacks identified in the research include a loss of timeliness in field operations, decreased autonomy in decision-making, more complex management, potential problems with lenders and split lines of credit, and difficulties in unwinding the arrangement should the partners desire to do so.

Because joint owners of an asset do not bear all the wealth effects of their decisions regarding that asset, joint ownership inherently produces conflicts of interest (Holderness 2003). The

remainder of this entry discusses five overlapping categories of potential conflicts associated with shared use and ownership of an asset: scheduling of use and timeliness concerns, moral hazard or free-riding problems, costs of collective decision-making, opportunism and hold-up problems, and risk.

Scheduling of Use and Timeliness Concerns

One of the more obvious potential conflicts that may result from shared use of farm equipment is disagreement regarding who has use of the machine when. Crop yields and quality are impacted by the dates of planting and harvesting. Since the window of optimal timing for farming operations is often short and can be highly uncertain due to weather variability, timeliness is a critical issue. The value of losses due to bad timing is difficult to measure, but can certainly result in lost revenue due to less than optimal yields and quality (de Toro and Hansson 2004; de Toro 2005; Larsén 2007). The timeliness issue may be compounded when sharing occurs over some distance because of the time taken to transport the equipment to partners' field. On the other hand, significant distances between sharing partners may alleviate this problem if planting or harvest windows do not overlap. Farmers may experience fewer weather delays in farm operations if fields are more spread out. In addition, if pooling resources allows sharing partners to afford larger, higher capacity equipment, timeliness issues may not increase and, in fact, may be reduced if coordination of use is not too cumbersome (Edwards 2009a, b).

Scheduling of equipment use to minimize, or at least reduce, timeliness costs can be achieved in a variety of ways. Contracts that include stiff penalties for failure to deliver the equipment can incent partners to hold to negotiated dates of transfer (Wolfley et al. 2011). In situations where sharing partners are geographically proximate, timeliness costs can be alleviated by treating all members' fields as one large operation and scheduling use on an "as ready" basis or by devising a rotation system that takes advantage of

differences in land types (e.g., higher ground is typically ready to be worked earlier than lower ground (Artz et al. 2010)).

Moral Hazard or Free-Riding Problems

A free rider is a person that benefits from an effort contributed by other members of a group without contributing sufficiently himself. Free-riding problems may occur in equipment sharing arrangements when one or more of the partners involved do not contribute their fair share of equity, do not contribute a proportionate share of labor (an effort moral hazard problem), or do not provide adequate care of the shared machinery (an asset moral hazard problem). These situations occur when there is asymmetric information, in particular, when any individual member's benefit is determined by the joint effort of the group, and it is difficult to verify the actions of other partners because effort is not perfectly observable. When an asset is shared, users of the asset may have incentives to overuse or misuse the asset because they do not take into account the full value of the asset if they own only part of it (Holmstrom and Milgrom 1994; Holderness 2003; Holmstrom 1982). Wolfley et al. (2011) provide the following example: "a moral hazard problem, for example, may arise when one producer agrees to perform maintenance on the machinery as stated in the contract, but only performs the maintenance shortly before delivery rather than according to the manufacturer's recommendations." The effort moral hazard problem may become more severe as the number of partners increases because each partner shifts effort from farm to off-farm activities (Allen and Lueck 1998).

Monitoring can help ensure that other members are careful with the shared equipment or are contributing an agreed-upon number of hours of work when labor is shared, but it may be costly (Allen and Lueck 1998; Larsén 2007). Allen and Lueck (1998) find that when production is seasonal and there are many stages to production with few tasks, monitoring costs are high, and partnerships are relatively rare. Larsén (2007) contends that social norms, peer pressure, and dynamics

(repeated interaction) can mitigate the moral hazard costs involved in sharing arrangements. She concludes that when there is a high degree of trust among partners, the perceived moral hazard problems are negligible.

The free-riding result rests on fairly strong assumptions about the inability of partners to observe one another's efforts. In reality, one likely can tell how much effort partners are putting forth (although imperfectly), so some amount of "horizontal monitoring" or informal policing through peer pressure is possible and effective at preventing free riding. This is more likely when partners are located in close proximity to one another, as opposed to sharing over long distances. Sharing equipment with a neighbor, or neighbors, facilitates observing one another's behavior on a regular basis. Personal relationships among the collaborating farmers make free riding more costly in terms of social norms (Larsén 2007). Furthermore, repeated interaction with partners sharing arrangements that exist over time (multiple years) provides incentives for producers to act in good faith in order to maintain the relationship. In cases where monitoring is more difficult, such as sharing machinery over long distances, well-written and enforceable contracts can help solve free-rider problems.

Costs of Collective Decision-Making

Joint use or ownership of farm equipment requires some degree of joint decision-making by the partners involved. Collective decision-making can be costly, not only in terms of the time involved but also because it may result in inefficient decisions, particularly when individuals in the group place their own interests above the interests of the group as a whole (Hansmann 2000).

Sharing equipment with other farmers decreases autonomy and reduces flexibility in individual members' decisions. While some types of equipment may allow for a degree of variation in cropping systems across member farms, other equipment might not. In these situations, collaborating farmers need to decide on a common production system. Brand loyalty or

loyalty to particular suppliers can cause conflict and may prevent members from realizing other potential benefits of their cooperation, such as savings from bulk input purchases. If labor is also shared, the off-farm commitments of individual members may cause disagreements about the timing and amount of contributed labor (Artz et al. 2010). Conflicts of interest and inefficiency of collective decision-making can prevent quick responses to rapid changes in conditions which can be problematic in farming due to its weather-dependent nature and high levels of uncertainty.

Collective decision-making is easier, less costly, when the interests of group members are well aligned. This emphasizes the need for finding like-minded partners with whom to share equipment. Also, devising relatively efficient methods for making decisions such as delegating information gathering and other tasks to individual members or committees and establishing voting procedures can also significantly reduce these costs.

Opportunism and Hold-Up Problems

Sharing equipment with other farmers could create situations for opportunism and hold-up problems. Opportunism, in a broad sense, refers to a willingness to act in self-interest at the expense of another party (Love 2010). In the context of sharing a piece of farm equipment, one member may act opportunistically by failing to deliver a shared combine to his partner at an agreed-upon date, for example, if weather delays result in an inability to complete harvest in a timely fashion. In somewhat larger groups, a majority of group members could act to exercise their right of control in the decision-making process in such a way that members in the minority are harmed. For example, a majority of younger members could vote for the group to undertake significant investments in new equipment. Members looking to retire or leave the sharing arrangement in the near future might not realize the returns from the long-term investment.

Hold-up problems, or situations in which one party to a contract holds some economical bargaining power and uses it to exact concessions

from another party, can also arise in this context (Cai 2003). This may be especially likely when members' preferences, or resources, are not well matched. Hold-up problems can occur even without opportunism, in cases where unusual or unanticipated events render the current agreement obsolete (Love 2010). For example, even among farms of roughly equal size, differences in land productivity, or a localized weather event, could create a situation in which partners' financial resources diverge. As a result, they may disagree about when to replace or sell a shared machine, with the dissenting farmer effectively holding up his partner(s).

Additional Risk

Entering into a joint ownership arrangement can effectively tie the outcome of a critical farm operation (e.g., harvest) to another person's decision-making and behavior. In this way, partners in equipment sharing agreements can expose themselves to additional risk. A partner may not uphold his end of the bargain to deliver a shared machine on time or may incur a loss that has impacts on other partners. For example, individual default could lead to a collective liquidation of the asset. Well-written and enforceable contracts or a high degree of trust among partners can mitigate some of this uncertainty.

Summary

Shared use of farming equipment has the potential to improve farm business performance by enhancing profitability, lowering risk, and reducing invested capital. Yet, the costs associated with the variety of possible conflicts inherent in the joint use of an asset render the practice relatively rare. Nevertheless, interest in equipment sharing may grow as machinery costs rise, and the level of technical knowledge and skill required for production increases. It is unlikely that widespread adoption of these models for sharing machinery will occur given their complicated nature unless solutions for resolving conflicts are devised and

disseminated. Future work should therefore be aimed at developing practical strategies for reducing or eliminating these potential conflicts involved in shared use of an asset.

Introduction

The prima facie ethical problems surrounding the cultural practice of luxury dining are obvious enough. A market for great luxury implies great wealth disparity and is essentially classist. The fact of luxury dining entails that some significant

measure of the wealth of the better off is used for their own optional enjoyments instead of for the benefit of the needy. Luxury dining typically involves the extraordinary use of animals, for arguably frivolous human pleasures. It can also involve uses of land and energy resources that are inefficient, unjust, and unsustainable. Luxury dining arguably involves a very inefficient use of human capital as well, consuming countless labor hours that might be better spent helping to solve real problems, in order to tantalize a lucky few. In a world in which human malnutrition and poverty are widespread, enormous wealth is concentrated among the few and powerful, inhumane treatment of animals for food is routine, and unsustainable and inefficient agricultural and harvesting practices abound, luxury dining as a cultural practice must, from an ethical point of view, stand suspect at a minimum and perhaps be convicted. If a practice is suspect, then so must be its practitioners and perhaps chief among those its founders. One such founder of the current practice of luxury dining is the subject of this essay, the chef and father of modern French *haute cuisine* Auguste Escoffier. So it must be conceded at the outset that, from a variety of perspectives, Escoffier's contribution to ethics may well be negative.

But the ethical significance of a practice is more than just its overall tally on the ledger sheets of justice and the good. Ethics broadly conceived concerns the conditions for flourishing – excellent – human life. Cultural practices are in substantial part constitutive of situated human lives and thus represent opportunities for pursuing and attaining excellence of the self. Individual and collective pursuit of excellence within a cultural practice also advances the practice itself and may significantly contribute to the advancement of the social life in which that practice has its place. Striving for excellence within, and the advancement of, cultural practices is moreover a paradigmatic exercise of practical rationality, and so the development of new cultural practices provides opportunities for human beings to realize most fully their distinctive and highest virtues. The development of cultural practices in the context of new kinds of lives, careers, artistic expressions, and social arrangements, each with their own distinctive normative dimensions and opportunities for excellence, may

therefore be a significant contribution to ethics in this broad sense. In this light, Escoffier's contributions to ethics are substantial. Moreover, not only did Escoffier make substantial contributions to the development of a cultural practice, he did so in a way that was itself virtuous, with significant degrees of generosity, charity, and respect and concern for others, thus setting standards of excellence not only within his profession but for the conduct of that profession itself. These contributions, as well as some of the ethical concerns they bring with them, will be the focus of this essay, which begins with a brief sketch of Escoffier's long and productive life.

Life

Auguste Escoffier (the "Georges" which often precedes the "Auguste" was a nickname) was born in 1846 at Villeneuve-Loubet, in Provence. At the age of 13, he was apprenticed to his uncle's popular restaurant in the nearby resort city of Nice, there gaining his first experience of the hot, unsanitary, rough, and slavish life of the restaurant laborer. He was also exposed to wealth and its demands for excellence. Having completed his apprenticeship, Escoffier left Nice in 1865 for a position at the esteemed restaurant Le Petit Moulin Rouge, in Paris. He began service as a lowly kitchen assistant under Chef Ulysse Rahaut, who, though a tyrant typical of his metier at the time, recognized ability and ambition; he steadily promoted Escoffier through the ranks.

In 1870, the Franco-Prussian war broke out, and the Ministry of War, in need of cooks to serve the headquarters of the army of the Rhine, conscripted Escoffier, then on active reserve, from the Le Petit Moulin Rouge. During the campaign, Escoffier faced constant pressure to produce meals for a moving encampment with few provisions. He learned how to make much from want, wasting nothing. France lost, the army of the Rhine was taken, and Escoffier was encamped with hundreds of other prisoners of war near Mainz. Food was scarce and conditions deplorable. But Escoffier soon managed to get himself appointed as chef to some aristocratic French officers whom the Prussians had interned in luxurious villas in Wiesbaden.

In 1873, Escoffier returned to Paris and Le Petit Moulin Rouge, taking over as chef de cuisine from the departing Rahaut. He introduced radical kitchen reform, banning the consumption of alcohol and the use of loud and vulgar language. Le Petit Moulin Rouge thrived and was a draw for royalty and celebrities. Around this time, he began his friendship with the actress Sarah Bernhardt, which would last the rest of her life. He also began experimenting with the preservation of foods, especially the canning of tomatoes. Tomatoes were a principal ingredient in many of his dishes, along with garlic – he was a true Provencal – this latter to the delight of his clients when they were unaware it perfumed their fare and often to their horror when they found out.

In 1884, Escoffier, now married to the poet Delphine Daffis and running the kitchens at the famed Maison Mairé in Paris, received the summons that would make him a star. The Grand Hotel in Monte Carlo had lost the services of its valued chef. The hotel's director, and ambitious Austrian of humble origins named César Ritz, reasoned that he might as well seek out his departed chef's *maître*, who happened to have been Escoffier. Ritz made Escoffier a generous offer, which the chef accepted. Neither "Ritz" nor "Escoffier" was a household name at the time; both would soon become so.

It was at the Grand Hotel that Escoffier became persuaded that the complicated display system of the Grand Cuisine of the time, in which numerous elaborate and varied dishes were served to tables all at once, should be abandoned and replaced by a simpler kind of cooking, with meals tailored to the desires of individual diners. His conversion was total and zealous. He began revolutionizing kitchen organization, recipe design, menu composition, and even table setting to suit the new style. His motto was "*faites simple!*" He also ramped up his writing career, which had more or less begun in 1883, when he cofounded the *journal L'Art culinaire*, to which he contributed for many years.

One client of the Grand Hotel was the impresario Richard D'Oyly Carte, who had been made rich and famous by his productions of Gilbert and Sullivan operettas at London's Savoy Theater (James 2002, p. 113ff). D'Oyly Carte lamented

the state of London hotels and dining and hatched a plan to remedy the situation: he would build a new hotel in London of the most opulent style imaginable, to go along with the Savoy Theater, and he would get Ritz to run it. Ritz's price was as follows: an astronomical salary, 6-months-a-year leave to pursue his own interests, and Escoffier to run the Savoy kitchens. Ritz approached Escoffier, who, daunted by the idea of dealing his French *cartes* to English tastes, reluctantly agreed to set up the Savoy kitchen and train the staff. Escoffier expected to be at the Savoy for some several months. He stayed for about a decade.

The labor of putting together a proper French kitchen *à la* Escoffier at the Savoy was enormous, especially since the dismissed staff had trashed the place before departing (Escoffier 1985). As Escoffier expected, winning the English over to French cuisine was a considerable challenge. His efforts were ingenious. For example, he tricked the English into eating frog's legs by coyly naming them "cuisses de nymphes" (nymph thighs). He also knew he could not trust the English, or even the English headwaiters, to order a dinner intelligently from an extensive *à la carte* menu of the sort he had devised. So, in an ironic turn back to the older style, he invented the *prix fixe* menu, a set meal devised by the chef at a given price. All the efforts paid off. The Savoy was a huge success, the place to be and be seen. Escoffier and Ritz were the talk of London society.

Ritz and Escoffier left the Savoy in 1898, under mysterious circumstances. But they were now in a position to do as they pleased. Ritz and his company set up the Ritz Hotel at the Place Vendôme in Paris and then the Carleton Hotel in London, with Escoffier designing the kitchens and menus and with the Carleton in direct and successful competition with the Savoy. Ill health forced Ritz into retirement in 1906. Escoffier continued his writing, publishing in 1903 his mammoth *Le Guide Culinaire* in 1903, a bible of French classical cooking still consulted by chefs around the world. He also sought commercial success with preserved tomatoes and a variety of bottled sauces and jarred pickles. In this as in so much else, he

was a pioneer of what is now a very common practice among celebrity chefs.

Escoffier helped establish the *Ligue des Gourmands*, an international culinary society that put on, to much press attention, elaborate multicourse dinners with identical menus of dishes from *Le Guide Culinaire*. He also helped found and contributed to the culinary journals *Le Carnet d'Epicure* before the First World War and *Revue Culinaire* after (James 2002, p. 228ff). Escoffier played the role of celebrity chef with vigor and panache, presiding over culinary exhibitions, lecturing, and arranging important dinners for aristocracy and royalty, including, on at least three occasions before the First World War, Kaiser Wilhelm II, who, so impressed by one meal Escoffier had put on, exclaimed "I am the Emperor of Germany, but you are the Emperor of Chefs." This oft published remark morphed into the title with which Escoffier's name has ever since been associated: "The King of Chefs, and Chef of Kings."

Escoffier retired from the Carleton in 1920, but remained engaged in sundry restaurant and commercial projects, and continued lecturing and writing. In 1928 he was made *Officier de la Légion d'Honneur*, the first chef to be so honored. 1934 saw the publication of his second major work, *Ma Cuisine*, with some 2500 recipes. On February 6, 1935, his wife of 56 years, Delphine, passed away at their Monte Carlo home. Escoffier followed her 6 days later.

There is a sad, but necessary addendum. Escoffier's and Ritz's departure from the Savoy has long been a matter of mystery. It was hasty, and no obvious reasons were made known. Beginning in 1984 (Barr and Levy 1984), the English journalist Paul Levy has alleged that Ritz and Escoffier were dismissed on the grounds that they had been wooing investors for Ritz's new Carleton Hotel, which was to compete with the Savoy, at the Savoy's own expense. Levy alleges, and there is corroboration for these allegations, that Escoffier signed a confession that he took illicit commissions – kickbacks – from the hotel's suppliers. To what extent this confession is merely an admission to what would have been unremarkable business as usual at the time, and

obtained by the Savoy only to defend against the possibility of a suit for wrongful dismissal, is unclear.

Elevation of the Profession

Escoffier insisted on a level of dignity and decent working conditions for kitchen staff that was unprecedented. The caricature of the angry, shouting chef who rules by terror and berates his staff still has some truth to it, but it was very much the norm of mid- to late-nineteenth-century France. Escoffier insisted on a quiet kitchen, in which the chef could speak rather than yell his orders and still be heard. Indeed, given the other changes in kitchen practices he initiated, this was necessary. Escoffier demanded the highest standards of sanitation in his kitchens and of his workers. Food preparation areas were to be spotless and tidy, as were the cooks who worked in them and their standardized uniforms they wore. Working neatly and cleanly became acknowledged virtues. He believed that cooking is a dignified craft, worthy of an artist, and of great social importance. He treated his colleagues in a manner consistent with this and made considerable efforts to ensure that professional cooks were taken care of in their retirements and old age – even the tyrant Rahaut (James 2002, p. 218). Rather than protect secrets of his own success, as a tradesman might do, Escoffier self-consciously spread them, so as to improve the lot of diners everywhere and the dignity and conditions of those who cooked for and served them. The success of Escoffier's restaurants, and the comprehensive and progressive training he provided to his employees, meant that the practices he instituted in his kitchens spread into industry standards. As Hegel pointed out, it is only within the constraints imposed by norms or standards that freedom and creativity become meaningful. By generating and propagating new standards for how a professional kitchen ought to be run, Escoffier made it possible creatively to excel at meeting those standards.

Escoffier's collaboration with Ritz had lasting social impact. The union of luxury and modernity of both bed and board, the attention to elegance and detail, and the uniformity of that standard throughout the Ritz chain of hotels had never

been equaled. Their Savoy was the first public establishment in England at which it became fashionable for the aristocracy to dine and to see and be seen. Previously, British men of means or title dined primarily at their clubs, and it was thought shameful for a Victorian woman of character to dine in public in the company of men. Ritz and Escoffier, bringing continental customs across the channel, changed that forever. Men now wanted to dine publically at the Savoy and its imitators, and, if modestly attired, women could join them. English women could thus be seen, could listen, and could even be heard in public gatherings in the same site as men of rank, power, and privilege (Ashburner 2004). American practice, as was so often the case, followed the English (Ritz and Escoffier collaborated on projects in New York and Pittsburgh). Possibly, this contribution to what might be called the publication of respectable women had some significance for the suffrage movement in England and the United States. In France, women had long dined publically in restaurants with men, so Escoffier and Ritz's ventures instigated no parallel change of practice there; French women did not get the vote until 1944.

Brigade System

Escoffier introduced and refined the brigade system of kitchen organization, designed on the plan of the military brigade – a command consisting of a number of battalions variously deployed. Prior to this introduction, restaurant cooks tended to be responsible, either individually or in small groups, for the production of dishes from start to finish (the exception being the saucier, responsible for producing the four mother sauces on which all others were based). This prior system was highly chaotic, individual cooks each having to do the several steps their various dishes required and often needing to share, or compete for, the same heat source or equipment to do so. Under Escoffier's plan, the kitchen was organized around stations, each with its own dedicated staff, with the various steps of recipes distributed to the stations suited to their performance. The various components of a dish are prepared in parallel at the several stations and then assembled

on the individual diner's plate (or the serving platter, if the dish is finished tableside). In a large kitchen, there might be seven or more stations, e.g., *garde-manger* (larder), pastry, roasting, fish, *entremetier* (vegetables, soups and salads, etc.), and sauces, each with its own chef (*chef de partie*) and several cooks ("commis") and perhaps apprentices.

Nowadays, many professional chefs begin their careers in culinary academies. But it is well known that the best training a professional chef can receive is the sort made possible by Escoffier's innovation: rotation through each of the stations of a brigade, starting at the bottom. That way, you must do, and hence learn, everything. And given the hegemony of the brigade system, the skills learned are transferable to any comparable establishment. Even today, the most talented and ambitious graduates of cooking academies hope for a chance to make such a rotation, at the best and most professional restaurant kitchen that will have them. They follow a well-defined career path carved out by Escoffier. Prior to Escoffier, the cook had really only one route to something like real professional respectability: private service in the hire of nobleman. Escoffier is the first of the great French chefs to earn fame cooking for the public, as a restaurateur, as have almost all others after him.

Progress is rarely if ever without cost, and the development of institutional structures and practices yield new forms of oppression as well as flourishing. Thus it should be pointed out in fairness that the brigade system makes possible a kind of alienation through specialization. If a cook is not in fact rotated through the various stations, but is permanently posted to a particular task, they have not a career in which they learn, develop, and progress to the goal of becoming a chef, but the equivalent of a dead-end assembly line job. And in fact, most kitchen brigades, at least in the United States, are staffed not by aspiring chefs making progress through the ranks, but by low-wage, often immigrant, laborers, with little chance of advancement and a kind of permanently narrow skill set that would ill suit them for employ even as full-service short-order cooks. It is one thing to learn the craft of professional cooking through

serial exposure to all of its facets. It is quite another to spend 8 h a day, 5 days a week, 50 weeks a year cleaning lettuces, tossing salads, and slicing fruit. Where labor has no guarantee of a voice in the conditions of its employ, the brigade system can operate to limit as much as to enhance opportunities for flourishing.

Revolution in Menu and Service

The brigade system led to a number of substantial developments in dining style and practice. Before its advent and popularization, the so-called French service was the restaurant norm: all dishes, hot and cold, soups and roasts, and savories and sweets, would be brought to the table at once (or in a few stages, each featuring a full range of kinds of dish), in large portions of more or less ornate composition. Diners then would select the dishes that most pleased their eye. For large parties this might mean that a diner got to eat what was close to him or her. The finer the restaurant, the more numerous and elaborate the dishes served. The area in which a chef could best show off his talent was in presentation, and the spectacularly elaborate presentation was the glory of French culinary art. Often enough the dishes were pieces of architecture – indeed, famous buildings modeled in hard pastry, marzipan, lard, what have you – intended for show alone. Such *pièces montées* were the centerpieces of the Grand Cuisine of Carême. In contrast, in service *à la russe* – in the Russian style – diners are presented with dishes in sequence, according to the proper order of consuming them. This has obvious advantages: dishes are presented and eaten at their proper temperatures and in suitable order, and everyone at the table gets a share of each dish. But it has disadvantages as well, related to both timing and variety. Because dishes are prepared and plated to order, the diner must wait, and if a dish is very elaborate and time consuming to prepare, the wait will be excessive. So dishes must be comparatively simple. Variety also suffers because so much of the cooking takes place during the service itself: the same number of cooks can produce a greater variety of dishes in say, 8 h, than they can in two. While the Russian style service had been introduced to France in the

1830s (Tannahill 1988, p. 302), such limitation kept it from becoming widespread.

The brigade system compensates for these limitations by breaking down dishes into their component parts and thereby increasing efficiency. The various components of the dishes on offer are prepared in advance for optimal readiness and ease of finishing execution at the time an order is placed. Accordingly, each station in the brigade has its own *mise en place* (“put in place”). This preparedness, tailored to the exigencies of the offerings, makes the production of the dish once ordered vastly less time consuming. But it also permits each station to perform many more tasks of similar kinds at once, allowing for far greater variety in the dishes that can be offered and prepared on demand. Escoffier’s brigade system thus allowed him both to introduce the *à la carte* menu, from which individual diners select what they want to eat from among many choices, and to facilitate the rise to dominance of the Russian style of service and its variants. These are industry standards diners take for granted today.

The logic of the brigade system also has consequences for how a recipe can be written, leading to a new systematization and codification of classical French cooking. Escoffier’s recipes can be maddeningly terse. For example, the recipe for *Tournedos Rachel* – an elaborate dish of filet steaks on toast with artichokes, marrow, and red wine brown sauce – is a mere 41 words long. (Escoffier 1969, pp. 382–383). Since the dish is composed of its components, its recipe need only mention the immediate components and their combination. But those components might themselves be highly complex. *Le Guide Culinaire* presents the composition of elements into components and components into dishes in a near axiomatic fashion. This work gives the canonical versions of the repertoire of classical French dishes; it is intended for professional chefs, who still consult *Le Guide Culinaire* today.

The typical French home cook knows better than to try to attempt the classical dishes of the professional French kitchen. Part of Child, Beck, and Bertholde’s accomplishment in *Mastering the Art of French Cooking* (Child et al. 1961) was to

convince American home cooks that they could indeed produce many of those same dishes in their own kitchens. They did this by writing recipes for them that reintroduced the many steps Escoffier’s recipes left out and explaining clearly and in detail the techniques required to perform them. But that accomplishment would arguably have been impossible had Escoffier not systematized and codified the classical cuisine they then made relatively accessible. In this sense, Escoffier revolutionized not only professional but home cooking and dining as well, encouraging an increasing number of passionate amateurs to adopt fine restaurant dining standards as their aim.

The idea that food prepared and consumed at home should resemble food served from professional kitchens is potentially problematic, given the typical elaborateness and richness of much luxury and other restaurant cooking, as well as the tendency of restaurants to justify profitable pricing by means of excessive portions. Those who can afford the money and time it takes to replicate restaurant food at home may do so at considerable cost to their health; those who cannot may choose to forgo preparing their own food altogether, relying instead on unhealthy processed and fast foods. If a regular diet of simple, whole, unprocessed, fresh foods is healthiest, the restaurant meal is dangerous paradigm for what one should strive for at home.

Efficiencies and Consideration for the Less Fortunate

Escoffier was attentive to the fact that fine restaurant dining is a social practice requiring plenty while many have little. He knew, and appreciated, that his was an exclusive art possible only where there are deep pockets and a leisured class. He also believed that it, and he, ought in some way to serve the common people.

Excellence in cooking, as Escoffier insisted, requires fine, fresh ingredients, and this in turn requires that, to a great extent, the kitchen must start from scratch every day. For this reason, supplies must be readily and regularly available and purchasing precise and controlled. Waste is economically and ethically unacceptable, but in a restaurant dedicated to excellence and a new

start every day, it is inevitable. Escoffier did what he could to minimize it and, in the course, to make sure that those in need benefited from the excess luxury of those with plenty. When the quails' breasts alone figured on the banquet menu, the legs were saved for the nuns to collect for the needy. He extended the Little Sisters of the Poor a standing invitation to collect surplus every morning for distribution to the hungry, first at the Savoy and then at the Carleton (Escoffier 1997, p. 99).

During the war, Escoffier had witnessed and deplored the way that procurement contracts were awarded to lowest bidders, who were then so ill funded and otherwise unscrupulous that they failed to perform to the contracts' standards, to the detriment of the troops. He was convinced that this practice should be stopped, and the quest to induce the ministry to put an end to it became something of a crusade for Escoffier later in his career (James 2002, p. 192). He also witnessed the starvation conditions at the camps for rank and file prisoners in close proximity to the plentiful conditions enjoyed by their captured officers. In general, he had the feeling that the war had been badly mismanaged by the command, causing great suffering and defeat for the troops. Perhaps influenced by these experiences, Escoffier regarded the problem of poverty as one of mismanagement and distribution, rather than scarcity. He championed modern methods of food preservation that reduce spoilage, pioneering the development of canning, mass market pickling, the bouillon cube, and other forms of conservation. In an era in which highly processed, industrially produced, prepackaged foods have come to dominate the diets of a great many people, to the detriment of their health and that of the environment, and in a way that thoroughly alienates them from both the ultimate sources of their nutrition and the craft by which raw ingredients become food, this early participation in canning and processed foods must necessarily have a sinister cast. But it is unlikely that this constellation of problems could have been foreseen by Escoffier, who simply wanted to make palatable foods available in lean times and make a bit of money.

Escoffier's concern for the unfortunate extended to theory as well. His 1910 *Projet d'assistance mutuelle pour l'extinction du paupérisme* proposed what amounts to a tax-funded social insurance program for the old, infirm, and needy. The plan included a national lottery to fund the construction and operation of rest homes for the elderly and the suggestion that retired resident cooks be recruited to serve in the kitchens. It also included a call for the establishment of a confederated Europe and a cry against the funding of a standing peacetime military, the need for which arose precisely because of the independence of the various European states. These ideas anticipate the modern welfare state and the Eurozone.

Summary

Because of Escoffier's influence, restaurant cooking has become a respected profession, whose successful practitioners enjoy considerable esteem. He revolutionized the way luxury restaurant kitchens were organized and, in turn, the way restaurant dining is conceived. In collaboration with César Ritz, Escoffier brought a new kind of fashion to the world of gastronomy, thereby engendering considerable alteration of the social status it enjoyed and of the society that enjoyed it. Escoffier's writings have had a lasting impact, and in particular, his *Le Guide Culinaire* still serves as the definitive treatment of French restaurant cooking technique around which much professional modern Western cookery is built. He pioneered various methods of food preservation, with lasting impact. Finally, Escoffier was himself a charitable man publically concerned with the welfare of those less fortunate than his typical client.

Introduction: Ethical Problems in the Present Food System

According to the 2009 World Hunger Map by the World Food Programme, present world

food system has very serious problems as follows. More people die of hunger every year than from AIDS, malaria, and tuberculosis combined, and almost one billion people regularly suffer from hunger (www.wfp.org). Malnutrition prevents children from reaching their full developmental and cognitive potential, and one child dies every six seconds from hunger-related causes. On the contrary, according to the World Map of BMI (body mass index) 2011, the overweight (BMI more than 25%) area covers most countries of the world except Asia and Africa, and especially Kuwait and Egypt are classified as obese countries, their citizens with a mean BMI of 30%. These numerical values show that the imbalances of food supply due to access and availability and inequality of wealth around the globe are very serious.

Systematic approaches in solving the problems have been tried around the world. For example, industrial forms of farming informed by science improved the mass production of food and mass breeding methods, generally in the Northern Hemisphere, have been supplying abundant meat to consumers. However, even though advanced farming technology, industrialized agriculture, and stockbreeding have contributed to relieving global starvation, they have raised other problems, e.g., the unequal distribution of wealth and contamination or destruction of the environment.

In this entry, ethical activism as an essential and fundamental solution will be discussed. It is an essential problem in need of a fundamental solution and involves changing our eating habits and making food accessibility more relevant to everyone. From the viewpoint of ethics based on the biology of cognition, the causes of the problems should be reduced to every one's doing, and thus, its correction of wrong ways of doing or action is the most important (Maturana and Perksen 2004). It is not easy to point who are the responsible, but in the present world food system from product to consumption, the most responsible could be the people who live in affluence in any country. People in affluent have a duty to benefit the worst off.

Definitions of Ethical Activism, Food System, and Food Culture

The concept of ethical activism, on which there have few discussions, seems to involve the idea that in order to resolve collective action problems of a political nature, it is rather important to act in a way that produces effective results instead of simply stressing an awareness of the seriousness of the problem and trying to choose valid norms. According to this thinking, even though we have had many discussions about how the ethical norms should be established, the norms will not be justified without results from action and practice. That is, ethical activism emphasizes the fact that practice in company with actual activity verifies and validates an ethical theory. But for this, a radical question from the current cognitive science should be drawn: Is the effect of the activities limited to validation of an ethical theory?

Note, however, that activism in this entry has another basic premise about what constitutes “activities.” The idea of the embodied mind which is free from the Cartesian dualism (Varela et al. 1993) takes the viewpoint that the activities inside our body are the determining factors of all the processes, from feeling and thinking to decision and action (Johnson 2007). According to this, what should be stressed is how to calibrate people’s habit or routine in which numberless activities are from moment to moment linked to each other. A personal habit or a custom of a society is a patterned linkage of the activities. It means that in our approach to the ethical problems related to the food system, how to calibrate our feeling, desire, thinking, decision, action, etc., should be the main issues of our discussions, since it is believed that a new epistemology of food ethics and a new motive of effective practice can be set according to this calibration.

From that viewpoint, it is necessary to give attention to the concept “food system.” The meaning of a system is so comprehensive that it cannot be explained easily. But in brief, a system not only involves all the elements inside it but gives a direction to them. In a system, every element sets in its good position and harmoniously keeps a mutual cooperation and dependence with all

others, and thus, a system as a whole can dynamically take its course in which all its elements are ruled and guided, for example, the system theory developed by L.v. Bertalanffy in which a society or an ecosystem is regarded as a lived system.

According to this understanding, it is possible to call the food system a food culture, because the biggest system in human society is a culture. The food system is one of the representative cultures that exist everywhere and in every time. A present food culture of a nation is actually an outcome of a long tradition of food system, which involves various types of interchanges between human beings and foods from the nature. In other words, the meaning of food system includes not only a whole interaction between human beings and the nature such as agricultural production, distribution, consumption, and waste but also all the things or affairs that can exist or occur vis-à-vis foods. Therefore, it is natural to observe how our activities respond to the current food culture and also to discuss how we can intervene in the current system and direct it toward a more ethically healthy situation, that is, correction of inequity or recovery of surroundings in the world.

Ethical Problems and the Present Food Cultures

A food culture is a sociohistorical product of a long time-tested food system, and thus, a food culture of a nation or a place could be an optimized one for that nation. Generally speaking, the food culture itself, e.g., food system in medieval times or in the slavery in the ancient era, was not a great problem against the environment before modern times or pre-mass consumption time, even though food shortages have still threatened people.

However, at present time, every food culture diminishes its own features in the course of globalization and many Asian countries have experienced substitution of traditional food cultures for the Westernized ones or the Americanized ones. Rapid urbanization in most regions expedited mass consumption of foods, and the mass consumption also induced mass production through

new technologies. Such mass production and mass consumption brought about serious modification not merely in food culture but also the relationship between human beings and the nature. The serious modifications are interlocked with various kinds of problems that are extended from individuals' health problems to environmental contamination or destruction. It must be true that human beings, as eaters or as the subjects of food culture, have to take responsibility for the problems, because intemperate appetite and excessive eating and drinking have brought the serious causes to the problems (Singer 1995).

In this entry, it will be clarified what the detailed essences of the food culture are and a direction for further studies on food ethics will be proposed. Along with this, a discussion about how to develop a model for ethical activism for a better food culture, which proposes to reduce human beings' exploitation against the nature and to recover equality of food consumption in the global society, by applying that model from tradition of food culture will be given.

Three Orders of Food Culture and Embodiment of an Individual/a Society

Food culture means not only the foods (edible things) themselves but human activities related to them. This is because the concept of culture basically involves human activities including looking for foods and cooking them. Those human activities have a basic and general aim, that is, for survival. But that aim and effects of the activities are not limited to survival. They interface with nearly every aspect of human lives and their influences are so wide and deep because nothing can be done without eating. Therefore, food culture is the very beginning of all human affairs and is a prerequisite or essential part in an enormously ecological circulation of all human affairs. A sound ecology of our society is the basis of our survival and sustainability.

In order to easily advance our inference, it is necessary, by taking an anthropological research view, to classify the details of food culture into three orders as follows. The first is the order of

food to food communications. We can observe this as a kind of harmony among various foods which have been developed in a culture or a tradition, and thus, most of a traditional menu would be considered a good model of the order. The second is the order of foods to human beings/human beings to foods communication. In this order, we can observe the influence of food on health, temperature, mind, soul, etc. Note that this is related to our habit of adversely picking out food ingredients, cooking recipe, how to eat, etc. Finally, it is the order of human being to human being's communication with foods as the center. For example, this is related to with whom to eat, how to make social relationships by invitation to a dinner, what/how to talk in mealtime, and so on. Most human affairs do not seem to be free from these orders; rather, these orders have been providing causes to most human affairs.

These three orders are related to each other in a complicated way. Human beings' routine is in fact the limitless circulation of these orders. Therefore, it is natural to specify the routine rules of human living. In this context, a question should be drawn for developing the idea of ethical activism mentioned above. Is this circulation merely daily phenomenon? It may be more seriously influential on human beings. It is true to express the influence on human beings is organization of a unique pattern on their desire, thinking, decision, and behavior. In other words, it is natural to be called as a kind of accumulation effect or a kind of adaptation effect. According to the accumulation or adaptation, a figuration of a unique pattern on the mind and body, more exactly speaking embodied mind, is shaped. The process of the figuration is of course a process of human negotiations with social and natural environment, and thus, the result of the figuration of every person or every society is necessarily different from other's. The figuration is performed not merely on the individual but also on a community or a nation (Imamura and Imamura 2007).

Whatever food culture may be, it is actually the result of the figuration in a long-term process. All the human affairs cannot be free from the figuration. Carefully observing the contents and direction of the figuration is central. What the contents

and direction of figuration on an individual or on a society are will exert a decisive role in future human civilizations too.

In addition, it is necessary to consider how the three orders in one complexity of food culture embodies the individual as a personal and social being, the society as a cultural complexity, and the world as the sustainable assembly. Firstly, it is natural to focus on the effect on the result of action and reaction between food culture and an individual as a personal being. In this case, what draws attention is the way the food culture has embodied the individuals. Personal eating habit or personal division between preferred foods and avoided foods is the results of the embodiment. Secondly, it is also reasonable to focus on the effect of the result of the action and reaction between food culture and the society as a cultural complexity. In this case, that is how the food culture has embodied a society. Furthermore, there must be numberless interactions between human beings and the world. According to these interactions, the world is also changing itself as human beings are changing in various ways to make use of the world and simultaneously to adapt to the world.

These embodiments can be observed in any traditional culture in the world. Here, in order to exemplify the three orders, let me analyze them with examples from Korean typical food culture.

Korean Food Culture as the Figuration by Buddhism and Confucianism

Even though current Korean food culture is said to be very much transformed from a traditional one to Americanized one, most families still keep Korean traditional food customs in their daily lives. Most Korean food restaurants also do not exclude the traditional food culture. Generally speaking, Korean food culture is a phenotype of a long-lasting context which has been built by various civilizations such as shamanism, Buddhism, Confucianism, and Daoism. Korean food culture can be explained more analytically with the ideas of three orders expressed above. That is, the Korean food culture is the enacted one with entanglement of the three orders through a long

historical context. Here, what should be stressed by the concept of context is the history of figuration. This is actually a long-term process of reproduction of Korean food culture. Whatever food culture it may be, it is repeated through routine and the routine is strongly supported by rituals and ritual-like installation that pattern the behaviors of personal and social beings into a very typical system of customs. In Korean history, Confucianism and Buddhism seem to be the main influences/factors of the figuration and the reproductions. Korean history is said to have a long context of about 4500 years, and Confucianism and Buddhism have their history of more than 2000 years in the Korean peninsula.

If so, how have Confucianism and Buddhism exerted their influence on the present Korean food culture? Both of them have developed their own metaphysics combined with the polished system of rituals, ceremonies, and etiquettes for proper practices. That is why they have been able to dominate the food lives or food culture as well as daily lives of Korean people for so long time. In the lives of Korean people, there are innumerable things to consider, which can be traced to the two traditions. Here, according to the three orders, a few points which are typical to Korean food culture will be highlighted.

The First Order in Korean Food Culture

What should be observed from the view of the first order as food to food communication is the traditionally organized menu and harmonious relationship among the foods in the menu. This order in every place or every nation is the important basis of the food culture, and the order itself is a mirror of the interactions between human beings and nature. Korean food culture has constructed its own menu as the others have done in their own orders.

Some representative examples of the first order of Korean food culture are as follows: The first feature of the order is the clear division of main foods from side dishes. The second is fermented foods such as gimchi, soybean paste, and so on. These are established as daily essential

foods. The table generally shows vegetable-oriented diet rather than meat diet. Frugality of the table is respected and harmony among foods is also emphasized. The frugality means the restriction of the number of side dishes. The reason why the frugality is emphasized lies firstly in underlying wariness against the deleteriousness or sickness arising from loss of balance between foods and human body.

Maybe one of the Korean typical menus which shows such food to food order is “bibimbap” which is easily chosen on aircrafts affiliated to Korean companies. The “bibimbap” which consists of rice with wild herbs, little piece of cooked meat, and traditional red pepper paste and should be mixed together for eating shows a good example of respecting the frugality and harmony among foods.

The harmony means beneficial combinations for human health and lives and such combinations theoretically supported by Confucian metaphysics. According to Confucianism, every material has its own quality and properties, and the quality and properties can exert influence on the whole or parts of a human body. Confucianism, as a philosophical background, supports the food system with a kind of bio-cosmology; one ultimate principle with yin and yang and five primary substances as the substantial foundation of the ultimate cosmos give the food to food order harmony. Even other food culture of other region or society has its own philosophical background, but it is right to tell it is supported by its traditional religion or philosophy, for example, Indian food menu and Hinduism or Thai menu and Buddhism.

For example, green color of a food material exerts an influence of strengthening the function of the liver and at the same time regulates or assists to make a human being demonstrate the temperament of benevolence. On the other hand, red color does the similar influence to the heart or blood and relates to the temperament of courteousness. There are more and more cases. But what is important is that the combination or the harmony among the foods directs people’s bodily health and promotes a well-poised mind. In this sense, these combination and harmony among foods naturally have linkages to the second order.

The Second Order of Korean Food Culture

In relation to the second order, the teachings of Confucianism and Buddhism are the primary considerations. The teachings raise a fundamental question. What’s the purpose of eating? Of course, survival and health are the primary purposes of eating, but both teachings suggest a higher purpose, which must be connected to the ultimate purpose of human life. Confucianism teaches about the duty to fulfill one’s lifework and Buddhism provides a path *nirvana* (*nirvana*, an ancient Sanskrit term used in *Indian religions* to describe the profound peace of mind that is acquired with *moksha* (liberation)). Eating is a routine activity through which the lifework of Confucianism or *nirvana* of Buddhism can be achieved. Thus, so many taboo words or religious precepts have been given. This means that if food culture is not sound, then one cannot achieve the ultimate goal.

In this second order, excessive desire or appetite is not good for health or the achievement of the ultimate purpose. As one of the most intense desires inside human body, our appetite should be controlled properly, though, of course, it should not be suppressed to such an extent to be deprived of vitality. There is a similar instruction in the two great thoughts which have led Korean people to develop a typical food culture. The similar instruction is *ahimsa* which means no destruction of life in Buddhism and “selective taking of animal life” from Confucianism. Thus, what Korean people embodied as a main principle of food culture is the minimum consumption of meat that is necessary to build healthy bodies or to maintain sound lives.

The control over the excessive appetite/desire to eat is not just the control over inside activities but also embodiment of harmonious way of mind-body cultivation. In this order, both Confucianism and Buddhism teach the following: Immoderate drinking alcohol and eating meat are frowned upon, because to eat and drink should not be for pleasure-seeking but for fulfilling lifelong work. Buddhist Five Commandments including drinking of no alcohol and *ahimsa* and the Confucian memorial service practiced at every beginning of

mealtime are the ritualized social institutions. Like these, the instructions of the two great religious traditions are not restricted only to the maintenance of health. Rather, it is natural to tell that the two thoughts commonly have set an ultimate purpose for human being's successful life (Maturana and Varela 1980; Varela et al. 1993; Varela 1999). Of course, each definition of the two on the ultimate achievement is not the same as each other, but basic ideas of both are the same. The same idea between them is that only due to a longtime self-cultivation or self-organization, an individual can become an ideal being, like Buddha or Confucius, who is regarded as the representation of ultimate achievement and who had already experienced a stage of an enhanced being on the fundament of the harmony in mind and body. In regard to the second order, what should be emphasized is the fact that their achievement based on their control over the basic desire involving the appetite.

The process of self-cultivation is the process of self-organization, in which the subject embodies the true virtue of self-constraint. Activities of the body along with the embodiment are changing their direction from being pursuing delicious foods and nice drinks to allowing minimum meal ingestion in a degree that makes possible only self-cultivation with healthy body. Additionally to such people's mind, the nature is regarded as the object to give their respect in return for their getting vitality and fitness from the foods produced in the nature (Yoo 2011). That is much different from ordinary person's mind that regards the nature or foods as the target of attack and acquisition with greed. Therefore, an unexpressed but very necessary and basic principle is that the second order has its extension up to the achievement of the ultimate stage of the self-organization (Yoo 2011).

The Third Order of Korean Food Culture

In the third order, the order of person to person communication is reflected in table manners or the food rituals (not limited to preparation). The two great traditions have established so comprehensive

ritual installation in Korean society. These installations correspond to Korean people's routine practices and are embodied by Korean people. What exactly is entailed by embodiment? The answer cannot be simple, but what is definite is that ethics coupled with manners is very tightly obeyed. Until now, the most influential in Korean society are elders first, filial piety, faith between friends, etc. Such ethics together with manners are still influential with table manners. These cultural phenomena show Korean food culture has promoted communal spirit in daily ordinary lives as well as in official ceremony.

The effects of such table manners and rituals prepared with foods have not been limited within the communications of mealtime. In fact, the mealtime communications are the important parts of the whole life of a person in a day. In other words, the mealtime communications firstly with family and secondly with other people in society are bound to be repeated around 87,600 times under the assumption that a person can live until the age of 80. From birth to death, there could be no such routinely repeated activities. But I think such routinely repeated habits perform a more important function to an individual's self-organization than occasionally repeated thing does or a rare occurrence can do. If so, what is the function of the routinely repeated thing?

In reality, this question is also applicable not only to the third order but to the first and second ones. Accordingly, this could be a more comprehensive question to the effect or function of a food culture to human life.

Ethical Activism on the Basis of Cognitive Science

What is, with the concept of the ethical activism, originally intended in this entry lies on this point. The patterned activities like eating and living habits are very decisive to our self-organization and so we must reflect our daily food life and must look for the way how to regulate the intemperate appetite and how to reorient the habits toward getting a peaceful mind-body situation and harmonious living with the environment.

Existing ethical arguments have been continued with attention to how to make the ability to choose good norms and to apply them to action. Their way has an old-fashioned premise that the thinking and decision with the reason must be the absolute basis of morally good conduct. But connectionism, one of current cognitive scientific paradigms about human cognition, proposed an entirely different idea about human thinking and action. According to it, there is nothing like reason inside human being. Instead, there exist only endlessly repeated connections and ensembles of activities from the whole elements of body from the viscera up to the brain. The connections and ensembles are not perceived but various kinds of phenomena can be perceived as the results of the connections and ensembles such as feeling, desire, emotion, thinking, calculation, comparison, decision, and action. These phenomena are traditionally called activities of human beings themselves, too. But these activities are merely the results from the connections and ensembles of other kind of activities that are proceeding at a deeper level as brain or viscera. Our activities can be classified at least into two categories: implicit knowledge and explicit one. This classification is very important to understand the different levels of our activities and it is closely related to the categories of know-how and know-what (Varela 1999). In addition, the former is regarded to keep more sensitive response system to affordance of outer things. According to the latest researches, more parts of our daily activities are organized with the implicit knowledge than with the explicit one. The implicit knowledge is not innate but embodied inside and giving a direction to one's habitual behaviors. Actually, habitual behaviors or know-how as implicit knowledge is of great importance in putting oneself unconsciously into a certain moral mood or emotional mood which is the actual base of one's moral decision with using one's reason (Varela 1999).

Many parts of our ethical problems are related to the behaviors which are repeated automatically in routine life. With the current food system, many examples of implicit knowledge and affordance can be observed. For instance, think of the case of drinking habit of a man. To this man, alcohol

gives off more affordance than to a normal person. This means that the owner of drinking habit has a stronger directivity to alcohol than the normal person. Then, is this directivity innate or not? It is not innate but must be embodied by itself during more or less long time. And in the process of the embodiment, the connections and ensembles of inside activities from the level of brain, viscera, etc., by a gradual process, have been patterning the sensitive response system to alcohol. This change inside the man means that he has got a system of implicit knowledge to sensitively react to the alcohol, and as a result of the change, the system could manipulate the man inversely. Actually, the person cannot easily throw away the drinking habit. In this case, the directivity to alcohol is a kind of implicit knowledge which is not well designed and at the same time cannot be realized by the person itself, because the directivity operates in the subconsciousness level and the person realizes only the feeling of alcohol drink as the result of the directivity operation. If so, does the person have no method to recover nondrinking habit except being treated with medication in a hospital? Of course, the answer is different along with cases, but it cannot be denied that there could be an autotherapy. The autotherapy is not a special one but a very common or usual thing, that is, the correction of the habit. Even if another person gives a strict warning against the expected harmful situation and reminds the norms about abstinence from drink, the habit can rarely stop. In this context, a critical question can be drawn. If one knows what to do, then can the person do it? In other words, is to know what to do and to know how to do automatically joined? On the contrary, the correction of habit is an entrance to access the level of implicit knowledge and a way to interfere into the patterns of the connections and ensembles and give a newly corrected direction.

Therefore, it is the tacit knowledge that should be focused in the discussion about the ethical activism. Food culture ranges over both the levels of explicit knowledge and implicit one. Explicit knowledge involves how to cook, how to make out menu, etc., which are made by a person's considering. Implicit one can be observed in the old habits and unchangeable patterns, which

rather rules a person's consciousness and intention. Most problems arise repeatedly from this implicit knowledge. Subconscious direction and habitual routine actions belong to the tacit knowledge, which comes from the embodiment of the ritual-like patterns in daily life but rather make stronger influence on human behavior and whole life than the explicit one.

The present food culture of the whole mankind is actually mixed with various contexts, and there are some countries which have no marked tradition of food culture as Michael Pollan points out (Pollan 2007). In many cases of daily life, traditional instructions and rituals are neglected. The ultimate purpose of eating changes to pleasure/enjoyment from the lifelong work and thus not only mass consumption and mass waste but also mental depravation is making the deep-rooted problems more unsolvable.

Concluding Remarks

In fact, such food culture clustered with the three orders is easily looked in any region or society, and every regional food culture has developed its own food menus, diet treatment, and table manners. Even if there are many differences among food menus, every regional food culture has, keeping the three orders inside supported by a traditional religion or philosophy, developed its own customs which include how to maintain one's health, how to make harmonious human relationship, how to save foods, and how to make the earth and the nature sustainable. If not the case of a desperately poor country or countries suffering from starvation, most countries have developed and kept such customs until recent time even though among them still remains a kind of food material acquisition by a way of animal abuse, for example, foie gras in France.

Even most developed or developing countries have experienced, in the process of industrialization, important changes of their daily way of eating living from traditional food custom to a modernized one which regards economy of time and high-calorie, low-cost food as important, but such aspect began to be criticized as one of the main factors of

injuring personal health or destroying the humanity of a society, and thus, nowadays, anti-fast-food or anti-junk food campaigns, for example, slow food movement or LOHAS (Lifestyle of Health and Sustainability), are in response of many people and many regions. However, if an important thing should be added to, that is to recover or rebuild a healthful human relationship by breaking bread together with family or neighbors or friends enjoying glib talks. It means what is important is human relationship shaped around the table manner as well as food menu.

Therefore, as a conclusion, the most basic and necessary practice for a healthy food system is to rebuild the food culture by refreshing the eating habits or food customs. In addition, it is necessary to refer to the good tradition which has developed the polished system of rituals, ceremonies, and etiquettes combined with a complete metaphysics in every region or country. By doing so, figuration and reproduction of a good food culture will be feasible. Depending on this reflection, ethical activism will acquire its verity by setting up right habits and doing so in daily lives.

Summary

This entry has three targets from the viewpoint of philosophy and cognitive science. The first is to elucidate the food system with three orders of food culture. The second is to make clear the essence of the ethical activist approach to the present problems related to food culture. The third is to propose an actual solution of ethical activism. This entry is designed depending on the studies of Asian traditional philosophy, especially Confucianism and Buddhism and at the same time depending on the connectionism of Francisco J. Varela and others' cognitive science and the study on ritual practice and ritual installation by both of Imamura. Korean traditional food culture is analyzed and the main points of the tradition will be discussed as preferable methods for dealing with the present food system and food ethics. The main remark is to rebuild our routine referring to the main point of traditional food culture.

Introduction

Overweight and obesity, a moderate to severe accumulation of excessive fat in the body, result from an imbalance between calorie intake and expenditure, leading to an increased risk of developing heart disease, diabetes, and cancer. Emerging on an epidemic scale in the second half of the twentieth century, the problem of overweight and obesity with an increasing global prevalence resulted in 0.5 billion obese and 1.4 billion overweight adults in 2008 (WHO 2013) due to sedentary lifestyle and the changing foodstuffs and food trends and eating habits.

What has happened to our food? In the developed regions of the world, with the United States as the most prominent, it has become abundant, thanks to the improvements in agricultural production, and it has become diversified; higher in sugar, salt, and fat; and thus more tasteful due to the improvements in food processing industry. Thus, both the availability and the desirability of the food have increased, along with its energy

density; today there is a plethora of high-energy-dense food on the market. A well-known example of the effects of these developments have been observed with the emergence of fast-food chains: the rate of obesity among adults in the United Kingdom and among children in Japan doubled in a decade in which the number of fast-food restaurants in the United Kingdom and the fast-food sales in Japan also doubled (Schlosser 2001), consistent with the positive association detected between fast-food consumption frequency and weight gain in the long term (Pereira et al. 2005). And what about our meals? The breakfast has either been skipped or shrunk to a bowl of cornflakes; the lunch has been split into hourly snacks in number with each being almost equal to a meal in calories; and the dinners in front of the TV set in the living room function as the popcorn in the movie theater. The people who have gained excess weight at various rates, the sufferers of this combination of unhealthy food and unhealthy eating habits, use a variety of means to lose it, which is mostly the following of a weight-loss diet.

And, as a second and absolutely non-negligible group, there are the dieters who would actually – at least medically – do well enough without dieting at all. In contrast to the growing number of overweight people, the second half of the twentieth century also saw the emergence of the thin ideal, which for decades has promoted the thin female body through accordingly thin media figures including models, actresses, performers, etc. (Gard and Wright 2005). The thin ideal with varying impact on females from the teenager to the elderly, with a normal weight or who are slightly overweight, has caused body dissatisfaction and a subsequent need for weight reduction, which again is mostly tried to be achieved by following a weight-loss diet. The duration, frequency, and severity of such dieting depend on the extent to which the ideal is internalized.

Therefore, those who are overweight and those who think that they are overweight constitute together the customers of the multibillion dollar weight-loss industry today, which offers them so many products from multifarious weight-loss diets to equally various teas and supplements, pills, and preparations – advertised almost always

with one or more of the adjectives “quick, effective, organic, natural, and herbal.”

Dieting, Weight Loss, and Weight Cycling (Yo-Yo Dieting)

And these products are often introduced by irrelevant people. Endocrinologists, the medical professionals working in the field of endocrinology, metabolism, and nutrition, have given their patients advices on correct nutrition. In addition to these physicians, however, such advices are frequently given today by physicians from irrelevant fields or even by nonphysicians on the media, who call themselves, and are presented as, nutritionists, dietitians, or assertively enough, “experts.” Therefore the first of these titles, nutritionist, will be used in this entry, interchangeably with the words introducer or marketer when appropriate, to mention those who have a product or an assertion to declare about nutrition, weight loss, dieting, and the like.

Weight-Loss (Slimming) Diets

Nutritionists appearing on the media are well aware of the basic golden principles for a healthy life and weight, which include a balanced diet of all food groups, a healthy amount of water intake, a regular exercising, and a sufficient sleep; though these are now regarded by some as “clichés already known by everyone.” Both today and in the past when people were less likely to be overloaded with information on any issue through the media not so widespread yet, conventional medicine has been successful in health promotion with the practice of these simple principles. However, it is also noticeable to nutritionists and to any observer that the number of the people who want to lose weight and lead a healthy life has increased. An increase can also be observed in the interest in innovation and what is novel. Instead of being content with clichés, most people today want to lose weight without feeling hungry or changing their lifestyles and eating habits, keep fit without getting tired due to exercising, and feel vigorous without wasting time in sleep. There is a demand in society for new diets, new methods,

and new suggestions accordingly developed. Nutritionists who are aware of this trend and confident of their education, knowledge, and thus their ability to benefit the society with their original opinions generally give it a try. They know that the above mentioned well-established practices will continue to yield successful results when applied to; however, they also know that suggesting through the media what is unheard of will quickly provide them with the attention of those seeking new easy means to lose weight. In addition to financial and emotional advantages, an increasingly popular name means an opportunity to stand out among other nutritionists (or competitors, in terms of the weight-loss market) as a trendsetter and to reach more people (or customers, in terms of moneymaking by receiving them in an office – but not patients since most nutritionists are not physicians). Such attempts for attention become the generator of the information pollution encountered every day on the TV shows or the Internet, in which many “miraculous” methods allegedly capable of providing a specific amount of weight loss are introduced, including herbal teas and recipes, recently developed diets, and drugs, allegedly again, harmless and of natural content. And the original opinions vary enormously, to give a few well-known examples: some argue for having six (or eight or even ten) light meals a day to keep fit, while some insist that it had better be limited to three main meals. Some highlight that olive oil is the healthiest cooking oil while others find butter innocent denying its association with cholesterol. Vegetarianism has long had its advocates, who are now challenged more loudly by supporters of different diets based on animal products. The continuously increasing diet options lead to a great discussion and an even greater confusion over the issue. In the last few decades, probably no other domain of medicine than overweight has been so frequently intruded with so meddlesome claiming.

Appearing on a TV show or publishing a book or launching a website with technically no chance to examine or even see the recipient of the information, there would be no great difference between an oncologist suggesting a specific type of chemotherapy with specific dosage to all those

with cancer and a nutritionist suggesting a specific type of weight-loss diet with specific amounts of nutrients (such as “matchbox-sized piece of cheese and plain coffee in the morning”) to all those with overweight. However, when the popular weight-loss diets are considered, it is seen that a single diet is vigorously claimed to help everybody with weight reduction, with no restriction specified on the use of the diet with respect to the age, gender, and personal background of its prospective followers, including their diabetes status and history of any metabolic disorder. Whether the type of the diet be low carbohydrate, low fat, or low calorie and whether its developer be a physician or a nonphysician, how can one unhesitantly set forth a one-day, one-week, or one-month menu which is indubitably not equally appropriate for millions of people? More specifically, for example, how safe is it to recommend a weight-loss diet which encourages the *ad libitum* consumption of animal fat and meat relying on a restriction of carbohydrate intake to those with a high risk or history of coronary disease or hypertension?

At this point, one might argue that a single pharmaceutical, too, is introduced to the market for the utilization of millions of people with an associated disease. However, with proper medical practice and regulation, there will be nuances. First, it is, or is not, prescribed to patients according to the initiative of a doctor as a result of an examination and evolution process, not provided or presented to them by the producer itself. Second, when it comes to weight loss, an ethical physician would not resort to a pharmaceutical unless less invasively modifying the eating pattern or physical activity level of the patient is not possible or effective, whereas most weight-loss diet marketers make use of every advertising gimmick to lure the magic cure seekers. Third, pharmaceuticals are introduced with a set of directions and cautions concerning their use and users, and like other conventional medical treatments, they are produced after years of clinical research and observation – what about the advices and products of most nutritionists and diet developers, what is their scientific basis if they do not rely only on some personal observations and interpretations?

Every year, thousands of new weight-loss products from diets to drugs and books are introduced globally, but not an equal number of studies are carried out on the issue in the same period of time, which, at least numerically, means that a considerable portion of such newly emerged products is either a modified version of the earlier products with some scientific basis or just made-up in terms of scientific method.

A 2004 study by the US Federal Trade Commission indicated that, of the investigated advertisements of weight-loss products such as nonprescription drugs, dietary supplements, diet patches, creams, wraps, and devices, 49% in 2001 and 15% in 2004 contained at least one claim which were found clearly false and scientifically infeasible (FTC 2004). Advertising techniques included asserting a recommendation or endorsement from a medical entity and featuring figures dressed in a lab coat. The seeming improvement between 2001 and 2004 might be accounted for the encouragement of the media not to run advertisements with such claims being effective (however, unlike the United States, many countries still lack similar regulations to screen out deceptive advertising on the media). And, it should be noted that fabricating and marketing a false weight-loss diet is much easier and more low cost than it is for a false tangible weight-loss product. Because, to reach its willing target, a weight-loss diet only needs be read on a book, newspaper, or magazine or heard from the TV or the radio, whereas the availability of false products such as drugs, supplements, patches, creams, wraps, and devices is partly restricted by factors associated with their distribution and material production. In comparison to related products and services, a fabricated weight-loss diet is much more likely to encounter and get taken in by.

There have been studies indicating that the diets followed by millions of people and reported by its followers to provide benefit might actually be non-recommendable or clinically non-superior to other weight-loss diets in the long term (Astrup et al. 2004) or that there is no sufficient evidence to recommend for or against their use (Bravata et al. 2003), and it has also been reported that the same diets might be dangerously inappropriate for

some (Chen et al. 2006). However, a frequent argument of the followers of the popular weight-loss diets is “everybody follows it,” which is mostly ensued by “nothing bad happens.” In fact, no immediate “disastrous” results should be expected when a weight-loss diet that indeed causes the insufficient intake of a nutrient, for example, is followed, which will be often the case for even a “crash diet” characterized by severe nutritional deprivation. Because human body is a mechanism perfectly programmed to survive with an ability to synthesize many organic compounds and convert them into each other, unless it is exposed to prolonged starvation. Thus, the negative health effects of a specific type of diet might not be necessarily immediate and easy to observe or measure. Furthermore, not causing a disaster in practice – to be exact, deaths or irreversible negative health effects – does not constitute enough justification in principle for the existence of a weight-loss diet. In medicine, when a treatment is introduced for the utilization of a group of people, its introducer is obligated to submit scientific evidence indicating its potential to provide benefit; otherwise, it would not conform to the fundamental principle of beneficence of the medical ethics.

The above-discussed fact that many of those who show up in the field of weight loss are not health-care professionals might explain their unawareness of such principles, but does not make it acceptable. It is arguable that commercial products cannot be equated with medical procedures and cannot be expected to conform to medical principles; however, a weight-loss diet, just like a weight-loss drug or supplement, is a direct intervention to the state of health of an individual, which is exactly the case with medical procedures, meaning that it can be – or should be – expected to similarly fulfill some criteria and to have been produced in conformity with a set of principles set to maintain the well-being of individuals. Though often stated by the marketers of the popular weight-loss diets, neither “my diet has never been reported to do anyone damage” nor “I guarantee a weight loss up to 20 pounds with the formulas in my book” is a medically valid or even meaningful statement. An expected utility

for the majority does not mean proven utility or safety, as noted. Furthermore, reported efficacy does not necessarily mean true efficacy. Testimonials cannot be presented or treated as clinical evidence. When to introduce a product directly associated with health, one should be able to reveal a reference with a statement close to “this clinically tested diet has shown to provide a weight loss up to 20 pounds in a period of 3 months, compared to the control group.” However, this nearly seems to be a utopian expectation, given the current situation of the weight-loss industry.

On the other hand, success in weight reduction depends not only on the removal of the excess weight from the body but also on keeping it off. Many people who achieved to lose pounds through a low-calorie diet regain an equal or greater amount of weight in time. This generally results from a later failure to adhere to the dietary or lifestyle changes adopted in the weight-loss period. It is also partly attributable to an inability to develop self-monitoring skills and self-control over eating behaviors, equipments about which the weight-loss diets on the market provides no advice. Finally, the long-term success rate of weight-loss maintenance varies among studies, from reviews concluding that the majority of the dieters experience weight regain (Mann et al. 2007) to those indicating a greater percentage of successful maintainers (Wing and Phelan 2005).

However, some people experience a more distinct fluctuation in their weight, repetitively losing and regaining some of it in a relatively short period of time, a condition called as “weight cycling” or “yo-yo dieting.” Weight cycling is characterized by a repetitive failure to maintain the initial weight loss that is intentionally obtained during each cycle; however, it has no uniform definition, which complicates the assessment of the related studies to draw clear conclusions with respect to its effects on health. Although weight cycling has been suggested to adversely affect the immune system and to result in a lower resting metabolic rate (Hooper et al. 2010), being thought to complicate the future attempts at weight loss, it has also been reported that a history of weight cycling does not impede the future efforts to lose

weight, accounting the less favorable metabolic profile of weight cyclers for differences in body composition (Mason et al. 2013). However, aside from its possible physiological effects on the metabolic rate, its probable psychological effects such as disappointment and frustration might make it more difficult for an individual to start and manage another challenge to lose the regained weight each time.

Analyses have indicated that an individualized diet with an energy deficit of 500–600 kcal is one of the best options in dietary management of weight, and it has been stated that a greater energy deficit might trigger an urge to eat (Haslam and James 2005). A hormonal contribution to this urge is also possible, being shown that diet-induced weight loss is accompanied by a perturbation in hormonal homeostasis with an increasing level of ghrelin, which stimulates appetite (Sumithran et al. 2011). Indeed, a greater desire to eat is disgruntledly reported by most people on a weight-loss diet, which leads some to uncontrolled overeating following an unpleasant period of dieting and eventually weight regain. And the adversities become intensified and more frequent as an intervention becomes more radical. Taken all together, it is reasonable to suggest that an unhealthy diet causing a drastic deficit of energy intake, in order to promise a greater weight loss in less time, might pave the way to becoming a weight cyler, in addition to many negative health effects. And that kind of diets are a glut on the weight-loss market.

Weight-Loss (Antiobesity) Drugs

It therefore appears to have a potential of harm to health when the mind of the weight-loss diet marketers is infected with the intention of popularity and financial gain. And what happens when the weight-loss pharmaceuticals, argued for a few paragraphs before, are produced improperly; that is, when they are marketed with their effects not being clinically well studied and well observed enough?

It is noticeable that a back-and-forth pattern that has streamed through decades is associated with their use. Many such drugs have been introduced to, and soon afterward withdrawn from, the market: In the early 1930s, highly

toxic 2,4-dinitrophenol was introduced, and in 1938 it was withdrawn from the market due to many side effects such as cataracts, renal failure, and hyperthermia. Between the 1940s and the 1960s, amphetamine use prevailed with millions of tablets including those intended for weight loss. The 1960s saw the emergence of the thin ideal and the parallelly accelerated introduction of pharmaceuticals for weight loss. Phentermine was approved in 1959 and fenfluramine in 1973; 18 million prescriptions had been written for the two until the 1997 withdrawal of fenfluramine due to side effects such as heart valvular damage. Dexfenfluramine was short-lived being approved in 1996 and withdrawn in 1997 due to its association with heart valvular abnormalities. Similarly, sibutramine was approved in 1997 and withdrawn in 2010, due again to serious cardiovascular side effects. Orlistat approved in 1999 has managed to survive to date despite its reported potential to cause severe liver injury. This is an extremely brief history on the US weight-loss drug market only (Ertin and Ozaltay 2011), other countries have their own stories with related drugs, which would again include side effects, withdrawals, and negatively affected users.

The undesired results with these drugs from the 1930s to the 1990s cannot be deemed as historical empirical faults with weight-loss medication. They cannot be ethically deemed simply as empirical because their intentional introduction for the sake of moneymaking, despite their poorly studied side effects and mechanism of action, has cost lives, and they cannot be deemed as historical because they keep killing, as apparent from the news about deaths due to the use of either the now-banned drugs or nonregulated supplements, such as those from China. And this is because people who medically need to, or externally imposed to, be thinner seek effortless solutions, instead of attempting a more demanding fight against the underlying conditions (Swierstra and Keulartz 2011).

Weight-loss medication appears to have always provided modest efficacy versus considerable risks. Given the principle of non-maleficence, a physician is ethically obligated to ask this simple question before prescribing such a

drug: is it worth that? Is a modest result also obtainable by other means such as behavioral modification worth risking a set of known and unknown side effects in the short and long term? And for the nonprescription drugs, supplements, and all other similar products that comprise a large portion of the weight-loss market, individuals should be able to conceive of asking themselves the same question, which seems to be possible through creation of a general awareness.

Weight-Loss (Bariatric) Surgery

There have also been developed surgical procedures to treat obesity, introduced and then modified or abandoned, such as jejunoileal bypass. However, unlike the case with the weight-loss diets and drugs introduced and promoted by non-health-care professionals, the surgical treatment of obesity has remained under the control and within the practice of medical authorities, due to – or thanks to – the complexity of the procedures, and it has been considered as a last resort by both the physicians and the patients, as it ought to be. People should reserve a little of their wariness of scalpels for pills.

Summary

Weight-loss dieters fall into two categories: those suffering from perceived overweight and those suffering from actual overweight. Determination of the personal priorities with or without psychological support might be more convenient and effective for the first group, such as achieving an expected level of thinness versus maintaining a state of health. As for the latter, it is a fact that obesity is a serious health condition with its implications on health and is difficult to cure and cope with. Modification of the diet to reduce or control the caloric intake would be helpful for weight loss or management. However, such modification would vary by the patient-specific factors and can thus be brought following a detailed examination by a physician and only a physician from the relevant branch, not a popular weight-loss guru on a TV show who is actually a cardiologist, for example. This is not because these people are

never capable to make a sound suggestion on the issue, but because their suggestions need confirmation by relevant authorities.

A considerable percent of people with a complaint of, or complications due to, being overweight expect great success in weight reduction without great effort. This leads them to seek some sort of magic methods to provide weight loss and hence fuels the growth of the related industry. Every alternative, when it is marketed convincingly enough, seems to the audience to be worth to be given a try. But instead, more of an approach with rational skepticism should be employed. Individuals from both categories who seek help for weight loss and management should be knowledgeable with the identity, competency, and affiliation of those to whom they resort. Prior to using a weight-loss service or product, including weight-loss diets, they should seek an approval from trusted authorities and clinical evidence for its safety and efficacy, if any.

A non-individualized weight-loss diet developed without taking into consideration the age, gender, genetics, medical history, and personal and initial conditions of a patient is a threat to health. On an individual scale, consulting with a physician prior to using a weight-loss product could be preventive against any possible harm. On a mass scale, government regulations on the media both to prevent its overload with false advertising and to use it to raise the public awareness would work.

It has been suggested many times, as is mentioned here, that significant success in weight loss and management is obtainable by determination in simple lifestyle changes including dietary modification, such as elimination of high-energy-dense food with low nutritional value, and introduction of regular physical activity, at any level from attendance at a gym to a 15-min walk. The issue of dieting, including the practice of a diet intended for weight loss, must not be subject to underestimation or be left to the direction of non-medical entities. Because, despite the amazing achievements in many fields of medicine, a healthy diet is still one of the most powerful weapons of medicine to prevent and alleviate most ailments, as has been for millennia.

Introduction

In 1984 Bruce Colman wrote:

A new agriculture is growing in the United States. Born partly of the environmental movement of the 1960s and 1970s, inspired partly by the unending crises to which the American farm is heir, harking back... to the great conservation struggles of the 1930s... this new agriculture is being conducted by hundreds of people all over the country.

It involves people gardening without chemicals... It involves developing new ways to own farmland and to preserve it against the land-hunger of sprawling cities, malls, and highways. It involves new attention to the oldest faults of agriculture: its self-destructive tendency to wash away and sterilize the soil, to encourage deserts to develop where people have been raising their food, and to drive the best and the brightest... people off the land. (ix, x)

Several ethical trends converge in the Sustainable Iowa Land Trust (SILT): a land ethic, a food/organic ethic, a back to the land ethic, and a critique of corporate capitalism – all of which combine to create an innovative approach to affordable, healthy land, and food in a place largely vacant of both – the American Midwest.

Ethical Bases

Land Ethic

The sustainable component is most central to issues of agricultural ethics versus legal or organizational principles. SILT aims to enact the principles of a land ethic as Aldo Leopold articulated

it in his posthumously published 1949 book, *A Sand County Almanac*. The central tenet is that a thing is right when it contributes to the integrity and stability of a biotic community and wrong when it does not.

Writer and farmer Wendell Berry has elaborated on these ideas in his extensive writings. He (2012) contrasts the “land community” of Leopold with corporate industrialism which is indifferent to its sources in the land and says, “There is in fact no distinction between the fate of the land and the fate of the people. When one is abused, the other suffers.”

Stewardship for Berry means not only taking care of the land but also keeping people working on the land. As he told food writer Mark Bittman in a 2012 interview, “How are we going to get a population of people on the land that aren’t telling their children, ‘Honey, don’t ever farm. Get out of here as quick as you can,’ but ‘There’s a place for you here. You can farm.’?”

Many others including Wes Jackson and John Ikerd have written on the topic from the point of view of sustainable agriculture.

Berry claims a scriptural foundation for his ethics. David Rhoads of Chicago’s Lutheran School of Theology suggests that the concept of environmental stewardship comes from the story of creation in Genesis in which God gives people dominion over the fish of the sea, birds of the air, and the animals of the land (Gen 1:1–2:4). The Hebrew word that has been translated as “dominion” means “to take responsibility for” rather than “to dominate.” God created humans to be responsible for the wellbeing of the garden Earth. Thus, stewardship of creation is fundamental to our humanity (Rhoads).

Others base their ethics on a secular concern for resource management and human ecology. Still others base theirs on a rights-based approach derived from the idea of the commons, that all of the earth’s resources belong by right to all of its people, and that none should have privileged access. With the rights to use natural resources comes the responsibility for maintaining them, thus all are equally responsible.

Food/Organic Ethic

In the nineteenth century, rural food producers were forced into cities to work in industry and create urban populations that required food. This produced a food supply crisis caused by a dwindling rural population. The analysis of plant nutrients and the promise of a cheap supply of them appeared to be the answer. In 1909, the German Chemist Fritz Haber developed a process for producing from the air nitrogen that plants could use. Its chief use was in the manufacture of explosives, but it was also one basis for what we now call conventional agriculture that relies heavily on chemical nutrients nitrogen (N), phosphorus (P), and potassium (K). With these nutrients, plants can grow without soil in hydroponic systems or in depleted soils. The organic movement is a response to these developments. The ethic is one of balance, sustainability, and health as versus conventional agriculture’s emphasis on maximization of production.

Shortly after the introduction of chemical fertilizers in the early twentieth century, the genealogy of organic farming began in Europe with Rudolph Steiner and his biodynamic movement, in Great Britain with Albert Howard and Lady Eve Balfour and in the USA with J.I. Rodale and his son Robert Rodale. While different branches emphasize different details, the general ethic is based on the idea of creating rich, bio-diverse, healthy soils to produce healthy plants and animals to improve the health of the humans who eat them, without petrochemically based inputs.

In response to a group of German and Polish farmers who were concerned with the loss of soil fertility and health and quality of their animals in the wake of using chemical fertilizers, Rudolph Steiner developed an eight-part lecture series in 1924. It was published the same year and translated into English in 1928. This became the backbone of the biodynamic farming movement that aims to create diversified farms that generate their own fertility by organic practices that are ecological, holistic, and ethical in congruence with Steiner’s broader philosophy of anthroposophy. Founded in 2000 as a 501(c)(3), Yggdrasil is an

associated land trust that aims to preserve biodynamic agricultural land in the USA.

Albert Howard was a British agricultural advisor in India where he soon came to promote traditional Indian practices over those of conventional agricultural science. In 1931 he wrote a book, *The Waste Products of Agriculture* and in 1940 he wrote *An Agricultural Testament* and later others on soil health and organic agriculture that informed Rodale in the USA.

Lady Eve Balfour was another pioneer of organic farming in the UK where she established an experimental farm to compare organic with conventional methods. In 1943, she published *The Living Soil* and in 1946 she cofounded the Soil Association.

In the USA, J.I. Rodale left New York City and moved to rural Pennsylvania to found the Rodale Institute in 1947. The mission of the institute is, “Through organic leadership we improve the health and wellbeing of people and the planet.” The institute has long published the magazine, *Organic Farming and Gardening* and many related books to promulgate these ideas and offer practical instruction.

The American fast food industry developed after the Second World War in tandem with the proliferation of suburbs, automobiles, and highways (Schlosser 2001) and has been signaled out as a source of health problems in the USA. But fast foods are just one end, the consumer end, of an industrial food processing sector that also provides foods for grocery stores and restaurants. As obesity and diabetes rose to epidemic proportions in the USA, it became apparent that the industrial food system was implicated. In 1986, Italian Carlo Petrini started a Slow Food Movement to emphasize the consumption of locally produced foods that have been produced sustainably. Thus, it reinforces the organic ethic.

Back to the Land

A parallel dimension in the USA was the back to the land movement exemplified by Scott and Helen Nearing and popularized by their often republished 1954 book *Living the Good Life: How to Live Simply and Sanely in a Troubled World*. He became active in social movements

after his dismissal from the economics faculty at the University of Pennsylvania in 1915 and then in the 1930s began homesteading on rural land in Vermont while publishing many books, articles, and pamphlets (Saltmarsh 1991). The ethic is one of self-sufficiency.

Others in a similar vein were Paul Corey, an author who moved from Iowa to rural New York where he built his own house and grew his own food and wrote an instructional book to encourage others to do the same, *Buy an Acre: America's Second Front* and similar instructional books on building chicken coops and houses. Another was Louis Bromfield (1943, 1948) who lived in France for 15 years before returning to rural Ohio during the Second World War where he restored several farms that had been destroyed by conventional agriculture. He was convinced that national greatness was based on land and the prosperity of the people who worked it.

Synthesis

These pioneers of a sustainability ethic were educated, articulate, and energetic enough to publish copiously. In 1968, after touring communes, Steward Brand published the first *Whole Earth Catalog*. The catalog did not sell products but provided information on books and products that promoted the values of self-sufficiency, ecology, alternative education, and holism and thus brought together these several ethical strands.

Critique of Corporate Capitalism

The last ethical thread that informs SILT is the critique of corporate capitalism that comes from diverse sources from the nineteenth century Karl Marx to the twentieth century Scott Nearing and Paul Corey to the twenty-first century Woody Tasch.

Opposed to the land ethic and other ideas of stewardship is the market ethic that emphasizes short-term maximization of profit for corporate owners, management, and shareholders. This is the ethic that drives agri-businesses at all levels. The principle ideology associated with this ethic is what anthropologist Katharine Newman (1988) has called “meritocratic individualism,” the defining doctrine of middle class Americans that posits

that rewards based on merit and achievement are promoted in schools and universities by such mechanisms as the assignment of individual grades for scholastic performance. In fact, anthropologist Jean Lave (1988) argues that the chief function of schools in democratic social orders is to assign merit as opposed to the aristocratic method of assigning social stature by birth. Thus, many Americans equate individualism, markets, and democracy.

If the criterion for good is maximization of profit, then ecological values are excluded. Thus, the costs associated with environmental pollution can be considered external to the firm, “externalities,” and not counted in the corporate budget (Bakan 2004).

Apologists for this point of view often base their rhetoric in a sense of reality that derives from economics. Far from being a neutral science, however, economics, as anthropologist Dimitra Doukas (2003) shows, is an ideology that was self-consciously developed as a justification for the rapacity of nineteenth century trusts (a private for-profit homonym to nonprofit land trusts) that later became corporations to make their actions seem natural, inevitable, and acceptable.

Related is the notion that business is the appropriate means for managing any resource. Thus, America’s Land Grant agricultural colleges and universities have promulgated an ideology of farmers as businessmen and the accompanying idea of farming as extraction that was to be maximized to return the greatest possible profits to farmers. Berry illustrates this further when he describes these ag schools’ transition from offering courses on “husbandry” to courses on “animal science” and “agriculture” to “agricultural science,” thus substituting the relationship a farmer may have with a particular piece of land with a science that can be replicated on any piece of land. Thus, the Land Grant agenda fits closely with that of the burgeoning postwar agribusiness industries that produced fertilizers, herbicides, insecticides, and genetically modified organisms and provided a means for their collaboration in the development of agricultural technologies (Durrenberger and Erem 2015).

Iowa’s Current Situation

Iowa is one of the centers of industrial corn and soybean production. These products are primarily not for food but for fuel, fiber, and animal feed as well as oils and sweeteners for highly processed durable foods.

The average Iowa farmer is 58 years old and trending older. One half of Iowa land is owned by people over 65, one-third by people over 75. Land has been held and accumulated for decades, since many of these large family farms are the victors from the 1980s farm crisis when the industry and its land grant mouthpieces were echoing Secretary of Ag Earl Butz’s advice to “get big or get out.”

Many older farmers consider the profit they will make by cashing out their land as their retirement security and, if anything’s left, their children’s inheritance. Many of their children see it that way as well. Because the land is seen strictly as a commodity, not a food-producing or environmental resource, even siblings can become estranged over land inheritance. If parents keep the farm in the family, issues arise once they are both dead. When dealing with multiple beneficiaries, usually siblings, it is nearly impossible not to find one who would prefer to live on and farm the land, while others insist on selling it to reap the multimillion-dollar reward that often awaits them. This puts the farm-loving sibling in the unenviable position of trying to buy out his or her siblings at current market value. The siblings awaiting their cash reward are often working with a sense of urgency once the owners die. The basis for capital gains under US law resets as soon as the original landowners are dead, and these siblings have no interest in paying taxes on the appreciated value that can accrue from that day to the day they cash out. These scenarios only get more complicated when three generations are involved.

Fully 60 % of Iowa’s farm land is rented and a similar percentage of landowners live out of state. This is because land has passed into the hands of people who do not wish to farm it, but who use it strictly for income. Farm management companies aggregate such lands to rent 1 year at a time to industrial producers who then farm as much as

10,000 acres or more in a single operation. If industrial farmers have little interest in conservation, such renters have even less. (Community foundations have joined the farm management business by offering farmland owners the option of donating land to the community foundation which will direct the income derived from the land to the charity of the land donor's choice. Again, this benefit is based on the maximum profit to be gleaned from the land without any regard to the farm's environmental or economic benefit to its local community.)

Pressure on Iowa's land comes from two sources: urban and rural. By 2015, people seeking agricultural land, either for income or use, had bid up the price of Iowa's best farm land beyond \$10,000 per acre. Thus, even a modest acreage costs upward of half a million dollars. In addition, expanding urban areas have increased the price of land for development around towns and cities.

The size of Iowa's farms continues to increase as the number of farms decreases. With the industrialization of agriculture, local agriculturally based economic systems have been disarticulated and the small rural towns based on them have disappeared. Farms have become suppliers of raw materials to global corporations whose economic relationships are internal to the corporation rather than to the locale. This becomes evident at the consumer end of the system by the decades-long process of unique family-owned grocery stores and restaurants being replaced by much more "efficient" and standardized ones selling food from distant lands.

The intensive farming of larger and larger areas for industrial extraction has resulted in the pollution of Iowa's waters, the erosion of agricultural land, and the demise of rural communities. Taken together, these trends are deleterious to the natural environment, to the economy, and to the people of the state.

At the same time, a growing food movement has reached Iowa, and there are many young beginning farmers wishing to tap into this new local food enthusiasm and market seek access to land.

SILT was founded to bridge the gap between new farmers who need access to land and the current system that offers them no access.

SILT

In tandem with the development of industrial agriculture and urban sprawl has been the destruction of Iowa's natural environment. Iowa is the most ecologically altered state of the USA with only 1 % of its original prairie remaining. This has spawned an environmental movement to conserve and regenerate prairie lands. A number of organizations are involved in this undertaking including the Iowa Prairie Network, Iowa Environmental Council, Iowa Natural Heritage Foundation, Iowa Native Plant Society, the Nature Conservancy of Iowa, the Sierra Club, and a number of Audubon societies. These natural heritage conservation groups preserve natural lands from any form of development.

SILT, in contrast, is a farmland trust that conserves land from development but also for the purpose of producing healthy food sustainably. There are a number of farmland trusts in the USA. Twenty-eight of them have public support for the purchase of agricultural easements, but very few restrict production to food or define and require sustainability. The Land Trust Alliance, home to almost all land trusts in the country, provides services to such organizations such as accreditation and insurance against costly lawsuits by people who acquire conserved land at a low price but refuse to abide by the restrictions that resulted in that lower value. Land trusts use one or both means of conservation: easements and land ownership.

Easements are legal documents attached to the deed that allow certain rights in the land to be legally isolated from others such as the right to develop it. In principle, an easement endures forever, or in legal terms in perpetuity. Landowners continue to own the property and have the ability to sell it, but the next landowner must abide by the restrictions of the easement. Land trusts may also own land that owners donate to them and then may determine the terms of the land's use within the scope of the land trust's mission.

On land that it owns, SILT will offer long-term affordable leases to eligible farmers giving them the security of land tenure while removing the cost of mortgage interest, which can be significant. This takes that land permanently off the market and therefore out of the land speculation game. On land that SILT does not own but that has a SILT easement placed on it, the restrictions for healthy food production remove any market pressures from development or from commodity crop farming, reducing the value of the land significantly, at least for the foreseeable future. That reduction in value makes it more affordable than any of the surrounding land for every farmer who owns it in the future.

Thus, through SILT, beginning farmers may gain access to farmland without incurring the debt entailed by purchasing land.

Iowa's population is concentrated in cities and towns. SILT's mission to protect land to grow healthy food simultaneously reduces the cost of land for food farmers while making the food they produce more available to Iowans. SILT is even working with county and city planners across the state to develop relationships with developers to explore incorporating this kind of neighborhood-friendly, nature friendly agriculture into their development plans. When developers across the country attempted this model in the 1980s and 1990s, it failed largely due to the fact that homeowners' associations were put in charge of managing the farms. The high turnover and lack of farm management expertise among suburban homeowners contributed to the demise of this model. In SILT's model, the land allocated for a farm will be donated to SILT, whose mission and expertise will keep qualified farmers working the land, while removing any potential for future development of that land.

A commonly heard slogan in Iowa is, "We feed the world." This is false. Iowa farmers do not even feed Iowa, a state that imports more than 90 % of its food (Tagtow 2008). Iowa produces mostly corn and soybeans which are not for human consumption. Tagtow (2008, p. 2) concludes:

Current Iowa agriculture does not meet the food and nutrition needs of Iowans. Iowa does not grow enough of the key foods for a healthy diet. If Iowans

were to eat according to the Dietary Guidelines for Americans, significant acres of land would need to be converted from corn and soybean production to fruit, vegetable and dairy production.

A similar calculus for the whole planet would suggest that the best way to feed the world is to foster the consumption of locally produced foods. Such a policy, while ethical on many dimensions, is counter to US foreign and domestic policies that encourage the production of nonedible cash crops over local food. These policies are promoted by both the agri-industry corporations and the agricultural colleges and universities. The problem of world hunger requires not greater emphasis on industrial production of crops but rather people having access to land and water, and policies that allow them to produce food for their own locales. The market did not determine the current system so much as government policy, and government policy can also make it easier for landowners to donate their land for the public good, in this case healthy, ripe food close at hand for schools, hospitals, nursing homes, and grocery stores.

Conclusion

Mark Bittman (2013) suggests that the industrial food production system uses 70 % of agricultural resources to produce 30 % of the world's food, while small household level producers use 30 % of the resources to produce 70 % of the food and radically reduce transportation costs by producing locally. If productivity is calculated as people fed from an area of land rather than units of crops produced, then the US ranks behind China, India, and the world average.

But he also points out a great power imbalance between small producers and agri-industry and their allies. Thus, one function of SILT and other such land trusts is to address that imbalance in order to improve the world's system of food production so that it can better feed people rather than produce money for the few. Unfortunately, addressing this imbalance means reconstructing much of the local food infrastructure that has been dismantled due to vertical integration of industrial food systems. That reconstruction is

happening across the country with Community Supported Agriculture, food and producer co-ops, and food hubs, but it is a mighty job.

Given SILT's ethical roots in the land ethic, organics, and the critique of corporate capitalism, this sounds pretty utopian. Because SILT has no money to purchase land, some people laugh when SILT leaders say they are seeking land and easement donations. But most people do not laugh. They think about it. Then some step forward and donate their land. These Iowans are able to see the world through an ethic of meeting human needs rather than maximizing profit. When we see land for its value of growing food instead of growing money, the problems and solutions get radically redefined.

Introduction

The critical examination of complex ethical problems in food production has traditionally received little attention within the agriculture and agricultural biotechnology sectors. The lack of formal ethical assessment stems from a persistent view that increased food availability is an unequivocal moral good in light of the potential three billion additional people expected to be alive by 2050 (Hourdequin et al. 2012). Agricultural biotechnologies such as genetically modified organisms and intensive farming practices involving new chemical fertilizer and pesticide products, animal rearing, and milking techniques have often been

portrayed as morally benign practices because of the projected welfare gains to global civil society from abundant food production. By contrast, however, academic agricultural and environmental ethicists have highlighted a growing concern with the ethical issues embedded within new technologies and farming practices, problems which resist simple resolution because of the multiple ethical principles at stake, and the myriad stakeholder interests that must be negotiated within civil society.

For example, an ethically justified agricultural practice may emphasize the protection of ecosystems, animal welfare, or increase of low-cost food to vulnerable communities. Though each of these priorities has a basis in established theory, often policies and strategies to achieve these goals are mutually exclusive and no single concern obviously overrides all others. Disagreement will also emerge over the status of different “concerned interests” in the sector. For example, within some ethical traditions, animals, ecosystems, and even the land itself can be said to have rights based upon the intrinsic moral value of these systems, independent of human use. In other traditions, nonhuman life is construed as a resource to be valued in relation to human consumption; thus incompatibilities emerge between competing ethical perspectives established in different normative ethical theory traditions and between different interested parties within the agricultural sector.

Such problems are compounded by continual technological change which produces new and previously unforeseen ethical issues, which in the agriculture sector have notably arisen in relation to novel gene technologies used to tailor biological organisms. The development of genetically engineered organisms for food production has raised concerns in public debate not only over biosafety, industry accountability, trust in institutional governance, and consumer choice in relation to food-labeling systems but also over the status of living organisms and humans’ capacity to alter the fabric of nature (Thompson 2007; Melin 2004; Ridder 2007). These issues have caused a degree of *moral outrage* in countries such as the United Kingdom, stimulating the significant public controversy and the formation of community-based organizations

and action groups campaigning against global agricultural biotech firms. These political actions have prompted the governments of numerous European nations to engage in formal practices of participatory technology assessment (PTA) aimed at evaluating risks, costs, benefits, and multiple stakeholder values to aid science policy and legislation. Notable examples include the United Kingdom’s “GM Nation?” public debate of 2002, Germany’s Diskurs Grüne Gentechnik (discourse on green biotechnology) in 2001, and the BioTIK initiative – an expert ethics committee and the citizen-focused consensus conference approach of the former Danish Board of Technology (Hansen 2010). Together these PTA processes are aimed at providing civil society input into and oversight of controversial technology development practices and, through the involvement of various stakeholder actors, a degree of deliberative democratic control of technological regimes.

This entry examines a particular approach to PTA emerging in the agricultural biotechnology sector, termed the *Ethical Matrix*, developed by bioethicist Benjamin Mepham (1999). The Ethical Matrix (hereafter EM) aims to bring together a range of ethical principles and explore the implications of the application of each principle to a range of “interested parties” (sometimes referred to as “stakeholder groups”). The following sections of the entry explore:

1. The background to the Ethical Matrix as a technology assessment tool
2. The principles and stakeholders applied in the matrix and how they are chosen
3. How it can be applied as a decision-support tool

Background to the Ethical Matrix as a Technology Assessment Tool

Embedded within the assessment of technological impacts in the agriculture sector is a concern with systematic evaluation of ethical issues; and yet the stakeholders involved in these processes, be they scientists, agriculturalists or “lay” citizens, frequently lack the specific training and expertise to do so. A concern is therefore raised that simply

“getting people round the table” to talk about multiple and conflicting values and myriad ethical principles is insufficient to justify particular practices or policy choices, because such deliberation lacks clarity, philosophical grounding, and an appropriate analytical structure. This lack of clarity in evaluating ethical issues is, in essence, a competence gap within PTA. Thus, practitioners and theorists in applied ethics have sought to expand and develop a range of “ethical tools” designed to aid different participants in ethical evaluation.

Ethical Tools

The concept of an ethical tool implies a type of philosophical device that provides a decision-support framework or methodology for structuring and facilitating group deliberation on the ethical issues arising from a technology, policy, or practice (Forsberg 2007). An ethical tool must delineate the terms of the debate; facilitate ethical deliberation among a range of stakeholder actors who possess relevant technical, scientific, or policy expertise (but who are not necessarily trained ethicists or philosophers); and provide mechanisms to reach specific conclusions or policy recommendations to aid policy development, legislative oversight, or technology implementation practice.

The Philosophical Underpinnings of the Ethical Matrix

The Ethical Matrix is a tool to structure discussion and facilitates reflection upon ethical issues in relation to new technologies, policies, or courses of action. Schroeder and Palmer (2003) place the Ethical Matrix within what is termed a *Rawlsian* tradition of metaethics, whereby the emphasis is upon the *procedures* of ethical decision-making. John Rawls (1951) published an outline of a decision procedure for ethics, arguing that reasonable principles are required in order to determine which courses of action can be justified. Such principles, Rawls argued, must be consistent

with the considered judgments of any impartial and competent moral judge (who is capable of understanding the basic premises and thinking logically about the consequences of courses of action); and so such principles must adhere to a “commonsense rule” of being recognizable and uncontroversial to a rational and impartial individual who is not formally trained in philosophy. Mepham’s Ethical Matrix follows in this Rawlsian tradition, in the sense that it provides a model for people who are not philosophers to base their analysis of ethics upon familiar principles and commonsense rules.

A Principlist Approach

The Ethical Matrix is composed of two interrelated elements. The first is the establishment and application of a range of *prima facie* ethical principles that are commonly understood as relevant to the case in hand, and the second is a list of agents that have “interests” in the outcome of the case. In PTA, interested parties are usually referred to as “stakeholders,” though the Ethical Matrix broadens this definition to include non-human as well as human individuals whose interests might be affected. These two elements are then put into a matrix in order to outline and assess the interaction between them – stakeholders along the y-axis and principles across the x-axis – thus emphasizing the inherent compromise in ethical analysis between multiple and competing interests and ethical requirements (Mepham 1999).

The multiplicity of principles and interested parties makes the Ethical Matrix a fundamentally pluralist and principlist approach to ethical evaluation. It is pluralist in the sense that its appeal to a range of *prima facie* ethical principles contrasts with the various mono-theoretical approaches that have emerged in disciplines such as environmental ethics (such as those espousing an intrinsic valuation of nature). This pluralism shares common ground with philosophical pragmatism in applied ethics, built upon the recognition that different types of moral principles can be brought to bear on different problems and that these principles must not only be relevant to examining the

interests and actions and outcomes of/for different “stakeholders” or interested parties but also amenable to practical use and application by users. It is a principlist model in the sense that ethical justification is derived not from the application of specific theories but from a selection of principles as per the Rawlsian tradition. The use of principles is based upon the notion that they are commonly understood by a broad range of actors within society and thus have a broad degree of support from both ethical theories and within the cultural beliefs of the participants using the matrix. Principles therefore replace normative ethical theory frameworks so that the language and terminology of formal academic philosophy can be eschewed in favor of terms that are easily understood and hence can be used by a range of diverse actors.

The supposed strength of a principlist approach lies in the allowance of a stronger case based on one principle to outweigh a weaker case based on another in particular circumstances. This presents an alternative to monistic normative ethical theory approaches that tend to assert a single principle (or set of related principles) over others. A metaethical question then arises about the choice of principles to populate the matrix and how they are used in practice. Mepham (2005) asserts that the principles used in the matrix must:

- Be based in established ethical theory to give it authenticity
- Be sufficiently comprehensive to capture the main ethical concerns
- Employ user-friendly language as far as possible

In the first iterations of the matrix, the principlism of medical ethicists Beauchamp and Childress was directly imported (Beauchamp and Childress 2001):

- Autonomy – respecting the decision-making capacities of autonomous persons
- Non-maleficence – avoiding the causation of harm
- Beneficence – acting in the best interests of others
- Justice – distributing benefits, risks, and costs fairly

These four principles have become well established in the medical profession for guiding professional practice and decision-making in patient care. Mepham condensed this list further, substituting the two principles of beneficence and non-maleficence for a single principle of well-being – for simplification and because of the inter-relationship between preventing harm and enhancing quality of life. Autonomy and justice were kept, although in later revisions this justice principle was relabeled as “fairness” in reference to the Rawlsian concept of “justice as fairness.” Table 1 shows an example Ethical Matrix that applies these principles – comparing the different positions adopted in relation to biotechnology firms, farmers, consumers, and environment. This example matrix uses the three original principles, as Mepham did when applied to the agriculture sector in early case studies of dairy farming practice (Mepham 1996). Mepham initially stated that because these principles were well tested within medical ethics (and established in commonsense morality due to their representation of dominant normative ethical theories), if one were to change the principles used, then this would require significant philosophical justification. However, as the tool was gradually taken up by different theorists and practitioners to different case studies, a more contextualist approach to principle selection has emerged. Mepham has thus since amended the original assertion, with more recent iterations allowing for the substitution of different ethical principles when appropriate for different cases (Mepham 2005).

An example Ethical Matrix for genetically modified food crops.

The process of choosing specific principles, and hence how the ethical discussion is framed, remains unresolved, however. In early iterations of the matrix, principles and interested parties were defined in a top-down manner, in the sense that they were decided upon before deliberation started by the teacher/convener/facilitator that sets up the deliberative process. In later revisions and applications, the choice of principles and interested parties has itself been a participatory process, in the sense that the deliberating participants decide the terms (Irvin and Stansbury 2004;

Ethical Matrix and Agriculture, Table 1 Ethical Matrix and agriculture

Interested party/ stakeholder	Principle			
		Autonomy	Justice	Well-being
	Biotechnology firms	Intellectual property protection allowing innovation in the biotechnology sector	Encouraging low-cost solutions to crop farming, stimulating economic development for agrarian farmers	Improving the resilience of GM crops, increasing overall food production
	Farmers	Avoiding restrictions on patented crops	Fair bargaining power to regulate seed prices	Livelihood protection from crop failure due to insects and viruses
		Avoiding pressure/coercion from multinational agricultural biotechnology firms		
	Consumers	Transparent food labeling encouraging consumer choice on GMO consumption and access to information on GMO imports	Opportunities to participate in decision-making (like GM Nation?). Preserved rights to protest against GMOs	Government regulation of GMOs and biotech R&D. Monitoring and ameliorating potential health and environmental risks
	The environment	Integrity of “nature” – intrinsic valuing and protection of ecosystems from potential cross-pollination with GMOs	Proxy representation of environmental interests in agricultural policy by nongovernmental organizations	Maintaining biodiversity Protecting ecosystems from environmental degradation and resources depletion

E

Kaiser and Forsberg 2001), and so principle and interested party criteria are populated in a more bottom-up fashion. However, some of these parties represented within the matrix may themselves be deliberating actors, whereas others are not (or in the case of the environment or future generations, cannot). Thus, there is a potential imbalance, as certain interests are actually represented (by deliberating stakeholder actors) and others must be represented by proxy. Thus, there is a need for tools to fairly justify the choice of principles and interested parties represented in the matrix and to correct for power imbalances that may occur between them, in order to remove any bias that may emerge in policy outcomes where some deliberating stakeholders seek to skew outcomes towards their specific interests. Cotton (2009a, 2014) suggests that one means to alleviate this problem would be to take Rawls’s concept of a decision procedure for ethics further. He suggests that one should adopt the concept of “reflective equilibrium” to structure deliberation using the matrix. Reflective equilibrium allows deliberators to choose among the principles to be included through the use of an iterative process of

ethical reflection. Reflective equilibrium involves moving between a range of available principles and comparing and applying them to considered judgments, moral intuitions, and practical circumstance and then recontextualizing and choosing the principles for the matrix in light of such intuitions and judgments (Rawls 1951). This is a contextualist method of choosing principles, which grounds principle selection based upon the specificities of the case, rather than the top-down selection by an expert practitioner, and hence allows the user to more substantively justify why particular principles are used within the matrix.

Principlism and Ethical Theory

By adopting a principlist approach, Mepham argues that the principles in the matrix do not constitute an ethical theory as such nor does the matrix directly use ethical theories. The principles are in fact a set of moral premises intended to clarify and assist deliberation (Mepham 1999, 2005). However, in practice there are direct

similarities between principles and specific normative ethical theories, and so the principles could potentially be used as shorthand representations of broader theoretical frameworks. If so, the three principles can be understood as being roughly in line with three dominant philosophical perspectives in normative ethics: deontology (emphasizing personal moral duty), utilitarianism (emphasizing the maximization of aggregate welfare), and justice as fairness (emphasizing procedural equity in decision-making processes).

Though theories play a role in the matrix, the matrix is nonetheless intended as a tool for mapping out and discussing the issues underpinning a decision, rather than determining an ethical decision based upon a particular set of rules or adherence to a particular ethical doctrine. Mepham asserts that the matrix seeks to remove philosophical bias in influencing the decision outcome, allowing individuals to come to their own conclusions based upon philosophical reflection and rational argumentation, and is therefore ethically neutral in its intent (Mepham 2000). It is therefore situated within the procedural or discourse ethics domain of Habermas (1991), whereby the moral deliberations by rational individuals confer ethical value upon the resulting decision.

Using the Ethical Matrix in Practice

Within the matrix itself, the content of the empty cells can be populated in two ways. Firstly, it is possible for the individuals using the matrix to think through the consequences of the policy or decision under consideration for different stakeholders, and then write in those consequences. This format can prove useful when using the Ethical Matrix to teach agricultural and food ethics. By structuring an individual's personal reflections on the issue under consideration, the matrix requires individuals to think like each of the actors within the matrix's list of stakeholders. This requires moral empathy and moral imagination – encouraging the users to put themselves into the shoes of the affected party and consider the conditions under which each of the

ethical principles is upheld or violated. Each cell of the matrix therefore shows the interaction between stakeholder and principle, usually either in terms of behaviors and practices or outcomes and consequences depending upon the elements under consideration. For example, by imagining the position of an agricultural biotech firm, the user then attributes moral agency to the firm and will likely focus upon the ethical implications of different behaviors and practices that the firm is imagined to employ. By contrast, “the environment” could be construed as a relatively passive bearer of impacts (such as when ecological systems are harmed by pollution) or conversely as a set of physical conditions which, when altered, could in turn benefit or harm specific human actors (as is the case when examining the impacts of climate change on vulnerable communities). Thus, the imaginative process of moral reflection on the interests of “the environment” could focus upon the consequences of other agents' behaviors in relation to its protection or upon the secondary consequences of technological interventions in natural systems.

Though useful for individual reflection, the Ethical Matrix has also proved popular, and arguably more useful, when used by groups of stakeholders that represent a range of competing interests. Thus, it becomes a tool less for structuring personal reflection and more for facilitating group discussion as part of a technology assessment. In both the individual model and the group model, the matrix must draw upon both factual and normative information. However, as Jensen et al. (2011) assert, some facts may be relatively straightforward and go unchallenged, whereas others may stimulate substantial disagreement among those deliberating using the matrix. Structuring discussions by populating the cells provides a framework through which evidence, both factual and normative, can be challenged – emphasizing the controversial and contingent nature of ethical issues in the management of risk in new technological developments. Once completed, the cells of the matrix represent the outcome of a deliberative process in which synergistic or antagonistic relationships between principle and stakeholder emerge.

Decision-Making with the Ethical Matrix

The matrix has been used in a number of case studies, both to evaluate its efficacy as a decision-support tool and to develop substantive discussion of ethical issues in a range of applied ethics fields. The first multi-stakeholder applications emerged within the discipline of agriculture and food ethics. Practical cases evaluated the ethical issues related to dairy farming issues such as assisted milking technologies (Millar 2000), cattle transportation (Whiting 2004), and evaluation of novel or functional foods (Mepham 1999), alongside other environmental ethics-related concerns such as forestry management, (Gamborg 2002) bioremediation of radiologically contaminated sites (Oughton et al. 2003; Howard et al. 2002), and long-term management of radioactive wastes (Cotton 2009b). One particularly relevant agriculture-related case study concerns the assessment of GMOs in fisheries management (Kaiser et al. 2007). This latter study by Kaiser et al. (2007) was significant in that it evaluated the Ethical Matrix as a participatory tool used by both expert and lay users in evaluating the ethical issues surrounding the management of GM salmon. They observed that the Ethical Matrix proved valuable in structuring ethical discussions for both expert and lay participants, allowing all deliberating actors to contribute to the ethical debate. In particular they noted that a lay panel of participants which were initially skeptical of biotechnology ended up with a more positive evaluation of the potential use of GM salmon by the end of the process, and so the Ethical Matrix encouraged participants to distance themselves from preconceived ideas and judge on the basis of information and principles that are designed to serve the common good.

In each of the aforementioned case studies, the role of the matrix in decision-making takes different forms. Though the population of the cells through deliberative dialogue provides a useful framework for discussion, this alone is insufficient in making a decisive policy. The stages highlighted above allow the gathering of ethical facts, serving to map out and stimulate

deliberation. Additional stages are required if this is to be taken forward in formulating policy options and alternatives for agriculturalists and biotechnologists. One means to do this is to use the matrix to identify a series of “ethical impacts” and weigh them appropriately (Mepham 1999). This can be done by dividing the completed cells into two groups, showing the positive and negative ethical impacts – white boxes representing a respect for the principle with respect to that stakeholder and black boxes representing an infringement. This shows the areas where political action is needed either to redress injustices or uphold current values. A more detailed analysis would use a ranking of respect/infringement across a weighting scale, using the Likert-type numbering system, e.g., –2 strongly infringe to +2 strongly respect with 0 neutral (Mepham and Tomkins 2003). This ranking can be done in a participatory manner as Gamborg (2002) suggests, by using the matrix in expert-led consultation process in a panel session, similar in some respects to a citizen’s jury. An expert panel on the topic under consideration is put together and composed of scientists, biotechnologists, agricultural specialists, policy makers, lawyers, etc. Each presents their “client’s cases,” outlining the pros and cons for each group identified in the matrix. This is followed by participatory ranking in a manner similar to nominal group technique (see, e.g., Andrews 2013) – each panel member and member of the lay public audience holds a copy of the matrix. After the presentation of cases and ensuing discussion, each person indicates in each cell of the matrix, whether they feel that the ethical principle is likely to be upheld, violated, or unaffected by the proposal, using the Likert scale to rank their perspective. By collating these responses, it is possible to obtain a verdict on the ethical perspectives of the group on the issues identified and hence, i.e., a measurement of the prevailing ethical mood among the participants (Mepham et al. 1997). Such a model is democratically pluralistic, in the sense that it incorporates lay public responses, voting and weighting of issues, and hence can prove useful for participatory technology assessment.

Summary

The Ethical Matrix can fill a competence gap where citizen actors and other stakeholders need guidance in structuring deliberation on ethical issues around a technology, policy, or practice and in making firm decisions on courses of action, within the context of a participatory-deliberative decision-making process. As Oughton et al. (2004) assert, the matrix can be used to help identify the relevant information required for decision-making (i.e., the facts, values, and stakeholders involved), helping to avoid bias towards specific moral values and addressing conflicts between them in a systematic way. However, even with all relevant information and systematic representation of different values, they recognized that moral judgment must be exercised while also questioning who this moral judge should be. So the Ethical Matrix, like other emergent ethical tools, provides a useful means to structure deliberation on the ethical issues inherent in new technologies and food policies; however, such tools cannot substitute rational deliberation and reasonable moral action, and care must be taken when choosing the right “moral judges” to take part.

Introduction

When people choose what to eat, one of the main reasons is the taste of the food. Many people in the world do not have much choice in their diets given their poverty, but in the Western world, the average consumer enjoys an overwhelming variety of affordable foods. The focus of this entry is the role of taste in the food choices of those who do have a choice. With more choices comes more responsibility; deciding what to eat has a moral dimension as well since food choices have an enormous impact on the agent's health, the environment, and the well-being of other humans and animals.

The core puzzle posed by taste is its involvement in the most common and ubiquitous cases of what look like weakness of will. Many people find certain foods morally bad because of their presumed or genuinely harmful consequences. For example, one might intend to become a vegetarian if one cares for animals and wants them not to suffer. However, despite of the intention, the person may fail to do so because of her high preferences for the taste of meat. Other examples include the wish to eat healthier or less fattening foods, but somehow the intention gets trumped because one is unable to resist the good taste of those foods. Tastes thus seem to have much more motivating force than often acknowledged. The ethical dimension of the issue is evident when one considers the failure of large masses of people to eat foods that they know to be better for themselves, the environment, the animals, and other people.

The entry is structured as follows. Section “[What Is Taste?](#)” clarifies the notion of “taste.” Section “[Tastes as Reasons](#)” discusses the relation of tastes and reasons. Section “[The Puzzle of Unethical Food Choices](#)” introduces the puzzle of unethical food choices. Sections “[Bad Food Choices as a Consequence of Weakness of the Will](#)” and “[Bad Food as the Subjectively Rational Choice](#)” discuss two alternative answers to the puzzle. Section “[Are People Egoists?](#)” considers whether ethical egoism might explain the unethical food choices. Section “[Ethical Gourmandism](#)” summarizes Korsmeyer's ethical gourmandism which holds that the taste of food

depends on its moral properties. Section “[Is There a Duty to Train One's Taste?](#)” asks whether there might be a moral duty to train oneself to not prefer the bad foods.

What Is Taste?

By a food's “taste,” one normally means much more than what is actually tasted by the taste buds. What is meant corresponds rather to the notion of “flavor,” a sensation caused by a complex interplay of various sensory modalities, including taste and olfaction, among others (Auvray and Spence 2008). This entry follows the ordinary usage by taking “taste” to mean mostly flavor. Sometimes other aspects are included in “taste”; for example, the texture and mouthfeel of a food are an important part of how pleasurable it is to eat, so evaluations of “taste” (e.g., “corn chips are delicious”) can be made on the grounds of flavor, texture, color, and possibly other features.

It is well known that foods do not taste the same to everyone (see, e.g., Prescott 2012) which is why one also needs to talk about how something tastes *to someone*. This holds both for descriptive properties (e.g., salty, sweet) and evaluative properties (delicious, tasty, disgusting). In what follows, it is taken for granted that people's tastes differ so by saying that something tastes salty, bad, delicious, and so on; what is meant is that it tastes that way to the person under consideration. Finally, evaluations of foods do not depend only on taste but also on what is being evaluated; for example, sourness may be a positive quality in lemons but not in corn syrup (Korsmeyer 2012).

Tastes as Reasons

People act on reasons and may have reasons for actions even if they are not motivated to act on those reasons. This suggests one of the main classifications of reasons into *internal* and *external* reasons (also known as *subjective* and *objective* reasons). Internal reasons have motivational force and are hence connected to the desires and

preferences of a person; they are also *motivating* reasons. External reasons in contrast are reasons that exist for a person, say a reason not to kill or drink poison, without the person necessarily having any motivation to act on that reason or even know of its existence. Many philosophers take *moral* reasons to be independent of anyone's desires or other motivations (for a defense, see Parfit 2011). However, once a person is aware of the moral reason or has that moral reason, then it is an internal and motivating reason (for a clear exposition and criticism of this common view, see Schroeder 2008).

What kind of reasons can be provided by tastes? Suppose that a person is hungry and wants to eat (or thirsty and wants to drink: everything that is said here applies to drinks as well). Luckily they happen to have a certain good-tasting food in their fridge and they are aware of that fact. Ignoring all possible other reasons for or against eating that food, does its good taste provide a reason to eat it? Common sense clearly says "yes"; eating tasty food causes pleasure and everyone wants pleasure. The pleasure gained from eating tasty food offers a motivating reason to eat it as well as a *prudential* reason that recommends eating it.

Can tastes provide moral reasons? The answer depends on whether the ethical theory under consideration holds that pleasure is good and that there is a duty to pursue the good. Egoism would most clearly promote the idea that pleasure from taste gives a moral reason. Consequentialist theories often hold that pleasure is good but how much value there is in gustatory pleasure depends on the particular theory. It is not easy to see how a deontological theory could attribute much value to tastes except by citing duties towards oneself of which experiencing pleasures might be one. In any case, except for egoism, most ethical theories seem to hold that gustatory pleasure offers at best a very weak moral reason.

The Puzzle of Unethical Food Choices

If gustatory pleasures do not provide weighty moral reasons, one faces the following puzzle. Many people find certain foods bad; for example, they might consider the food unhealthy or its

production too harmful for the environment, other people, or animals. These people have an internal and motivating reason not to eat such foods. Moreover, suppose that not eating those foods is not merely something that would be morally good but optional for such a person; it is mandatory from the point of view of morality given their beliefs about the food in question. However, many of such agents do *not* change their eating habits because they enjoy the food's taste so much. Hence the puzzle: how can people be knowledgeably and systematically acting against their best moral judgments?

As was mentioned, some philosophers like Parfit take moral reasons to be independent of anyone's beliefs or desires. Such views hold that whether the puzzle of unethical food choices is a moral problem depends on whether the foods in question actually are morally bad. The puzzle thus has two important ethical dimensions: first, it shows a potential conflict in people's moral beliefs and their actions which is a problem of moral agency. Second, *if* there are morally bad foods which knowledgeable agents nevertheless fail to avoid, the problem becomes one of political philosophy and raises questions about public policies towards the bad foods.

Are there genuinely morally bad foods? Leaving aside the question of where the competing moral frameworks might differ, most views would agree that foods are bad if their production causes serious environmental damage, much suffering to sentient beings or health problems to their consumers. It is worth emphasizing that most foods are not intrinsically bad: the foods whose production currently has bad consequences could often be produced in a perfectly ethical way, and "unhealthy foods" are typically unhealthy only if consumed in large quantities or as a part of an unbalanced diet. Whether a food is unethical depends essentially on how it was produced, on the current state of the world in other respects, and importantly, on the quantities consumed.

Regarding the current production methods, the most plausible candidate for being bad food is factory-farmed meat. Industrial farm animal production, *aka* factory farming, has been shown to have extremely negative consequences to the

local and global environment, to the people living in the vicinity of the farms, to the welfare of the animals, and to humans generally due to the development of microorganisms that are resistant to antibiotics which is a consequence of routinely giving animals antibiotics to prevent them from developing illnesses (Pew Commission on Industrial Farm Animal Production 2008). Pluhar argues that any existing moral theory would morally condemn factory farming (Pluhar 2010).

Even if not factory farmed, producing meat is generally more harmful than growing vegetables. The livestock industry contributes around 20% of all the greenhouse emissions in the world (McMichael et al. 2007). Even if the animals lived an otherwise good life, they suffer in transportation and when they are slaughtered. Philosophers have defended vegetarianism on the basis of various ethical frameworks, for example, on utilitarian grounds (Singer 1990), or on the basis of consideration of the rights of animals (Regan 1983). However, even if one accepts that there is nothing wrong in principle with killing animals for food, the current amounts of meat that is consumed are a huge burden for the environment (Cafaro et al. 2006). There is also a correlation between health problems and meat consumption (see, e.g., Crowe et al. 2013; Rohrmann et al. 2013). Hence, large quantities of meat can be considered bad food.

Finally, some foods have little nutritional value but provide a lot of energy. Obesity and its consequences are a major risk for individuals as well as for societies in terms of health-care expenses. Increasing sugar intake has been shown to increase the risk of type 2 diabetes irrespective of obesity (Basu et al. 2013). Foods that are high in sugar are thus bad foods when consumed in large quantities. Also, given the sedentary lifestyle of most Westerners, foods with high calorie contents may easily lead to obesity. Hence, the typical snack foods (chocolate, cookies, candies, potato chips) and sugary sodas are bad foods to people who do not burn the calories obtained.

The above examples show that unethical food choices are not merely a problem of moral agency but also a genuine moral problem: there are foods with undeniably bad consequences given the way

they are currently produced and the amounts consumed. In what follows, the focus is on the puzzle from the point of view of moral agency, and hence, what matters is not the actual badness of a food but what the agent *believes* to be bad; for simplicity, let us call the latter “bad food.” There are broadly two lines of explanation to the puzzle which will be discussed next.

Bad Food Choices as a Consequence of Weakness of the Will

The first and the most common real-world explanation relies on the idea of weakness of the will. The view explains the puzzle by saying that people often fail to act according to their best moral reasons since they are not enough strong-willed to do what they think is the best. What happens is something like the following: the person judges that there is most reason not to eat bad food. But when she is grocery shopping, she feels a powerfully motivating desire to eat something really tasty. And before the reflective mind (or the will) has time to intervene, the shopping cart is full of bad foods. The call of gustatory pleasures can thus trump the judgments of what is best to do all things considered. The agent ends up acting irrationally, against her best reasons. The inability of the will to resist the pleasures of tastes is probably one of the best and most common cases in favor of there being weakness of will.

This view raises several difficult questions. An especially hard question is how the weak-willed action came about. The views which hold that one can only act on reasons one is aware of will have to say that there was no reason for the action, only a cause. Alternatively one needs to distinguish between “competing minds” which have competing reasons.

The competing minds assumption is by no means as straightforward as it seems. For one, it seems reasonable to suppose that each person has just one self. So if the will is the self, who or what is the part of the self whose urges to eat must be resisted? As intuitively explanatory as the idea seems of the self being occasionally hijacked by one’s “primitive” wants, selves seem to be partly constituted by one’s deep desires, fears, and other such features. As long as one is not talking about

eating disorders or genuine food addictions (if there are any), the weakness of will view may construe the realm of reasons and the self too narrowly.

Bad Food as the Subjectively Rational Choice

Another line of explanation holds that the apparently conflicted agent simply has stronger reasons for not giving up bad food than they have in favor of change. This view denies that people act irrationally when they do not follow their avowed best reasons and hold instead that they are actually acting according to their best reasons. The puzzle is solved when one recognizes that people may be mistaken about what their best reasons are, and in fact, the best guide to the reasons they have is to see which reasons best explain their actions. A similar line of thought has been defended by Socrates (Plato 1997) and Hare (1952).

The link between the agent's best reasons and rationality was discussed above in connection to the weakness of will view which held that in not acting for her best reasons, the agent is being irrational. But that can mean two things: that the agent is being *subjectively* irrational or *objectively* irrational. The weakness of will view need not be committed to the agent being objectively irrational; as Arpaly has argued, sometimes an agent is in fact doing the most objectively rational thing even if she did not do what she thought was the best (Arpaly 2000). In contrast, subjective rationality has to do with the coherence of the agent's reasons and actions rather than with the objective goodness or validity of those reasons. The view currently under discussion holds that a person cannot be *subjectively irrational* since they always act according to the best reason, whether they know it or not. Since reasons are what guides actions, it cannot happen that one did not act for one's strongest reasons. Call the view under consideration the *subjective rationality* view.

Suppose this view is correct. That means that if an agent fails to give up bad food for its taste, then tastes are actually extremely strong reasons to her. Given the setup of the puzzle, the agent *believes* to have the best reasons to give up bad food. But since reasons motivate, if she does not act as her alleged best reasons tell her to, then she is

mistaken either about the reasons she has or about the strength of her reasons. To her the best reason is in fact gustatory pleasure which to her weighs heavier than the reasons she has for taking the food to be morally bad.

The subjective rationality view has some interesting consequences. First, since it allows that people may not know their reasons, it does not need a sharp distinction between reasons and causes. Second, it offers a simpler and more optimistic view of persons: we have just one self and there is no weakness of will. If one acts in ways that appear unwilling to the person (and she is not under drugs or otherwise manipulated), then she simply needs to take a good introspective look and try to find her true reasons for why she acted the way she did. The view thus holds that one's own reasons are not transparent to one and therefore one may be mistaken about them.

Are People Egoists?

If the subjective rationality view is on the right track and the food choices of the unethical agents reveal their true reasons, that suggests that their gustatory pleasure is a stronger reason to them than, for example, their health or the well-being of animals or the environment. Probably the only moral position consistent with such an attitude is ethical egoism which holds that one ought to do what is in one's own best interest. So given the failure of many people to change their eating habits despite of their trying, it is worth asking if the morally puzzling agents in fact hold the moral views they claim to hold, or if they just pretend to, or are under an illusion regarding their moral beliefs.

Pleasure is a powerful motivation, and delicious food causes great pleasure to many. So giving up pleasurable bad foods might be seen as too demanding a sacrifice since with the exception of damage to health, many bad foods are more harmful to the nature and animals than to the eater. People may thus believe in the badness of some foods but still value their own pleasures more. Such excessive valuing of the pleasures of food is traditionally known as gluttony. Tefler argues that gluttony is commonly behind unethical food choices (Tefler 1996, ch. 6).

Ethical Gourmandism

The previous discussion supposed that there are two separate dimensions which influence food choices: the moral properties of the food and the food's taste. However, Korsmeyer argues that at least in the case of a person who is cultivated and discerning regarding foods, a food's taste is affected by the food's moral properties. The view which she labels *ethical gourmandism* stands in opposition to the view in aesthetics which holds that aesthetic and moral properties of works of art are independent, and hence, a work of art may, for example, have high aesthetic value even if it is morally questionable.

Korsmeyer's argument depends essentially on the view that the evaluative properties of a food depend on identifying the food. There is empirical support for that, for example, from a study which showed how people's evaluations of a cold salmon dish depended on whether it was presented as mousse or as ice cream (Yeomans et al. 2008). There are plenty of ordinary cases too which support the view, for example, when someone is happily eating a pie until they find out that the filling contains snails which the eater finds disgusting.

However, such cases are also apparent counterexamples; since the person was happily eating the pie, was not she simply wrong in thinking it is disgusting? Korsmeyer avoids the problem by distinguishing evaluations of tastes from evaluations of tastes of foods (Korsmeyer 2012, p. 92). Thus, she could say that even if the ignorant pie eater finds its taste nice, it does not follow that she finds the taste of snail pie nice because to her snails are disgusting. If that is right, then food tastes have an essentially cognitive component to them.

The next step in her argument is that being a cultivated and discerning eater (a gourmand) requires knowing the origin and production methods of the foods since these are essential to discerning the tastes. She gives an example of a Scotch whisky whose flavor is described by an expert as follows: "The spirit has a fine, golden color, got from long years in cask in a dark, stone-walled, slate-roofed, earth-floored

warehouse above the river Spey. The nose is vinous, floral and smoky, like gardenias in a cigar box" (Hills 2000, p. 171; cited in Korsmeyer 2012, p. 93). Korsmeyer argues that to truly appreciate and discern the color and the flavors requires knowing the conditions in which the Scotch was produced since, as is illustrated by the description, the methods leave traces in the taste.

Given the cognitive component of evaluations of the tastes of foods and the requirement that a gourmand knows the means of production of foods, Korsmeyer argues that moral evaluations also influence tastes. Hence, if one condemns the force feeding of ducks for making *foie gras*, one should not enjoy the taste of it. However, such cases do occur; they are instances of the puzzle of unethical food choices. Korsmeyer holds that the agents of such cases are being inconsistent. Her suggestion seems to be that if one undergoes a careful scrutiny of one's moral beliefs and taste preferences, one cannot go on enjoying unethical foods.

Is There a Duty to Train One's Taste?

Unethical food choices are a problem of moral agency. But the problem becomes one of public policy if there are genuinely bad foods which knowledgeable agents nevertheless fail to avoid. For the sake of the argument, suppose that there are bad foods. Can people be blamed for their knowledgeably unethical choices? If tastes can cause even a moral person to act against what they take as their best reasons, maybe they just do not have the choice to act otherwise. So they cannot fight against the call of gustatory pleasures, but what is more, they cannot choose which foods cause them gustatory pleasures. As unfortunate as it is, most people prefer the tastes of bad foods.

The assumption here is that one can be morally blamed or praised for an action only if one chose the action. We have seen that the unethical food choices may be a consequence not of one's genuine choosing, but of either weakness of will or of unacknowledged reasons. Those people thus

cannot be blamed for their food choices, goes the argument.

Now, maybe people cannot resist delicious food, but they can influence what they find delicious. So even if one cannot be blamed for originally having morally bad tastes, tastes can be trained. Despite of the genetic basis of our tastes, the biggest factor in our preferences is habituation (Logue 2004). As Korsmeyer argues, we cannot blame the nature for our food choices since our tastes are a result of cultivation (Korsmeyer 2012).

If one is unable to resist bad foods, one may have excellent reasons to train one's taste so as to prefer better foods. By far there has been a contrast between two kinds of agents: those who think that the best reasons support giving up bad food and the explicit ethical egoists who think that they have a moral right if not even a duty to themselves to eat bad but tasty foods. The former agent certainly has a duty to train their tastes; not only will it ensure that they will make the moral food choices, but they are also causing themselves more pleasure by learning to prefer good foods.

Surprisingly, the egoist as well may have a duty to train their taste. This can be illustrated by comparing two egoists: one who trained their taste to prefer good foods and one who did not. During the taste training period, the egoist's gustatory pleasure diminished but once she is adapted to the new tastes she gets equally much pleasure out of food as before. In addition, she is healthier, probably weighs less, and hence looks better which matters to most people, and she might also be better off due to external consequences. And even if we suppose that good food can never be quite as delicious as bad food – for which there is no evidence – the slight loss in gustatory pleasure is certainly gained in pleasures coming from better health, and of all the pleasures, one gains while possibly living longer.

Summary

Nowadays an informed food choice must take into account the ethical considerations regarding the consequences of the food and its production.

Many people are unable to resist bad foods due to their taste even when they know it would be morally better not to eat them. This puzzle of unethical food choices raises questions on the role of tastes as reasons. Are they not reasons but merely causes which trump the best reasons of the weak-willed agent? Or are they in fact reasons not recognized by the agent? If tastes are the strongest reasons, that suggests that people might in fact be ethical egoists or gluttons who do not give much weight to the negative consequences of bad foods compared to the pleasure of tastes. The entry also asked whether people have a duty to train their tastes to prefer better foods and suggested that even an egoist has reasons to do so.

Introduction

Global agriculture and food production face a series of challenges over the next few decades. These challenges include growing food in a way that minimizes the environmental footprint of both plant and animal agriculture; producing renewable bioenergy to address the anthropogenic impacts of climate change (FAO 2011); producing safe, animal welfare-friendly, and nutritious food in sustainable and water usage responsible ways (FAO 2012b; Foresight 2011); containing invasive species and harmful pathogens and pests; balancing market conditions with rights and needs of people; and ensuring global food security and the viability of food and bioenergy production for whom it is a livelihood (see FAO 2009a, b, 2012b; Godfray et al. 2010). These challenges are intimately connected and require integration and synthesis of data collection, responsive public policy making, progressive regulations and management strategies, scientific and technological expertise, and layperson ways of knowing. Meeting these challenges will also require political will (in some cases), forward facing national policies around food and fuel, and information sharing and collaboration between global partners.

While the role of science, in particular agricultural and foods sciences (and their respective scientists), in meeting these challenges is critical, science by itself cannot meet the challenges mentioned here, since many of the concerns involve both values and ethical visions of how this generation of human beings intend to live and the kind of world they want to shape. These are normative questions that fall within the purview of *ethics*.

Ethics is concerned with values, virtues, principles, and customary habits and practices (Thompson 1998). It is the study of good and bad, right and wrong, and of the criteria that can help in both the evaluation and determination of right from wrong conduct and modes of living well. Ethical frameworks like the Ethical Matrix can be used to facilitate systematic dialogue and deliberation in order to solve difficult moral and

social issues in more inclusive and participatory ways. Ethical views are tied to moral beliefs and values. Values are ideas that are action guiding, serve as the basis for justifying actions and meaningful lives, and promote responsibility toward others. Values provide guidance to live well with others and for other private and public dimensions of human flourishing. Ethics functions to promote trust and sustain good relationships, which can also be instantiated through stewardship of nonhuman animals, the environment, and Earth's resources.

In meeting the abovementioned challenges, the agricultural science community (a multidisciplinary field that intersects with different domains – e.g., food sciences or natural science disciplines that enable food production and also politics, sociology, ethics, economics, and disciplines that produce nonedible commodities such as biofuels) must not only engage in research, innovation, and technologies and commodities development in agriculture. The agricultural science community must also engage with the ethical and value systems of the many publics who are impacted by global agriculture and production of food. Engagement with private industry seems critical too, and appreciating the business values and motives of productionism and market cum shareholder-driven priorities is part and parcel of the nexus between ethics, science, and profit seeking that dominates contemporary global agriculture. Where private industry is unable or unwilling to meet the public or common good dimension of agriculture, agricultural and food scientists working in the public domain will likely have to work with policy makers to engender public support for continued agricultural research, innovation, and product development in ways that distribute the benefits and burdens equitably among various stakeholders and which promote human dignity and flourishing across all regions of the world. *Ethical trust* between the agricultural and food scientific communities (which may have different impacts and influences in different parts of the world) and the world's public is central in order to address the global challenges mentioned above and the ones yet to be anticipated.

Why Is Trust an Important Ethical Issue for Agricultural and Food Sciences?

Trust, in the service of promoting and sustaining good relationships, is an important ethical issue for those working in the agricultural and food sciences given the types and magnitude of risks that the public may be exposed to every day from agricultural and food products and their attendant science and technologies. When it comes to something as intimate as food or nonedible agricultural products such as bioenergy that impact daily living, food and agricultural scientists are beholden to the public's "... attitude of optimism that the good will and competence of [the members of the agricultural and food sciences community] will extend to cover the domain of [their] interaction with [them, the scientists], together with the expectation that the trusted [scientists] will be directly and favorably moved by the thought that [the public] are counting on [them, the scientists]" (adapted from Jones 1996, p. 4; see also Limoges 1993). The reliance on or confidence in the good will of the trusted persons (such as experts, like scientists) is a three-place relation of "entrusting." The public trusts scientists with information, that they also have unique expertise regarding investigatory methods or processes, and with the possession of technologies that may impact their well-being, where the former grants scientists "discretion" to determine how best to steward information and/or resources (adapted from Baier 1986, p. 237). In the case here, this discretion leaves the nonexpert-dependent member of the public, morally, epistemologically, and physically vulnerable to the harm of being made worse through manipulation, negligence, and/or betrayal.

While not uniform throughout the world, efforts to select and improve crops and animals for high productivity through intensive agricultural practices since the 1960s have been adopted as the central driver for feeding the world and behind what is often thought of as "progress" vis-à-vis the Green Revolution. In intensification, research and development and advances in agronomy, animal sciences, and food sciences have been dominated by "productionism" and steered by utilitarian and market-driven values (Thompson 2010).

However, the utilitarian-guided productionism has been met with steady criticism for environmental damage and pollution, loss of biodiversity, and impacts on rural communities (Thompson 1995; FAO 2012b). Arguably, some form of intensification is needed to feed and provide energy for a growing world population which is expected to grow to be over nine billion by 2050. The emergence of novel areas of specialization and the complexities of modern technologies (e.g., waste treatment technologies, genomics, modern molecular biotechnology, genetic engineering, cyber and telecommunications) keep the public from knowing their food and other agricultural products more intimately, and thus, they must rely on the competence and good will of experts. Members of the public will extend trust, distrust, or remain agnostic depending on how they perceive scientists discharging their professional responsibilities. They may be highly distrustful if innovation comes at the expense of human rights and is not environmentally sound or sustainable or if the harms and benefits are not distributed equitably among the relevant stakeholders and if commercial products are not produced or traded in concert with scrupulous business practices.

Credibility is the moral capital of scientists and is earned or enhanced when scientists communicate openly with the public about their considered evaluations of the empirical evidence (Rollin 1996) or when they frame the relevant evidence in ways that help the public rationally to recognize the evidence for what it really is and how it may or may not impact their lives and futures. In an era of hyperepistemic dependency, ethical trust is an invaluable currency and can seem to be in short supply in many discourses involving *risk*. The hierarchical inequilibrium that exists between “expert” scientists and the public is characterized by vulnerability, since the latter lacks the appropriate expertise, ability, and education (Burgess 2004; Thompson 1986). These characteristics engender a power differential between the expert and members of the public. Thus, inculcating virtuous professional conduct and establishing codes of ethical practice are important ingredients in building and maintaining a trustworthy relationship between the lay public and the scientific community.

Ethical Trust and Risk

Increasingly, professionals in agricultural and food sciences who provide expertise to public policy making or whose research may have a large impact on society are asked to take into account the inextricable connection between what they do (be they bench or applied researchers) and the impact of what they do on broader social concerns and aspirations. Social acceptability of scientific processes as it relates to agriculture and its products revolves around whether regulations, policies, practices, and standards are grounded morally and validated scientifically (Lackey 2007; Doremus and Tarlock 2005). The presence of poor scientific methods in data collection, appropriateness of the study methods employed to gather data, and research design features like representativeness, biases, repeatability, uncertainties, and whether there is adequate transparency and lucidity associated with how the results of a particular study are derived, are questions agricultural scientists must confront about the efficacy and integrity of their science in the service of the public good. Professionals in the agricultural and food sciences must be cognizant that (i) the public (citizens and consumers) are concerned about who communicates what and when to them about edible and non-edible products from agricultural sources, (ii) that public policy makers are concerned about reliability of the relayed science in the name of protecting the public’s interest, (iii) industry agents are often concerned about the science that helps them promote their bottom lines, and (iv) producers rely on scientists to help them carve out an existence in this era of intensive food and nonfood production from agricultural sources. In a climate of uncertainty and risk, the underlying interests and values associated with the different groups create ethical tensions that need to be considered in the policy-making process in the event that agricultural sciences claims to be or is employed as an epistemological authority or arbiter (Thompson 1986).

Thus, *ethical trust* is highly valued despite the availability of information through the Internet and the relative ease (in most cases) of accessing

it and/or of finding “an expert.” The quality, reliability, and credibility of our sources of information and scientific content and decisions about what scientific studies should be funded, how scientific information should be communicated to the public, how data is stored and disseminated, and how science should be used to inform public policy are ascientific concerns that often have ethical and political implications and nuances (see Borner and Menz 2005). When trust is called into question, it seems natural to be concerned about and to scrutinize the nature of the expertise and raise expectations of what an expert should be, especially due to the risks that the public may be exposed to vis-à-vis the products engendered by the food and agricultural sciences (e.g., when food security, safety and quality, and public health are at stake).

Agricultural scientists are steeped in discourses associated with *risk*. According to Brunk et al. (1991) “a risk debate is not primarily a debate between those who accept the verdict of scientific risk and those who do not. . . Neither is it primarily a debate within science itself. Rather it is primarily a political debate—a debate among different value frameworks, different ways of thinking about moral values, different conceptions of society, and different attitudes toward technology and toward risk-taking itself.” The epistemic dependency and trust found in the expert-nonexpert relationship discussed above are emblematic of a “risk debate.” Furthermore, agricultural and food sciences are also informed by social processes, and scientists may find themselves making decisions that are either inherently normative or conditionally normative. “An issue is inherently normative if resolving it consists of endorsing a normative claim” (Brunk et al. 1991, p. 154). Those who are concerned about the presence of genetically modified foods in the food chain, for example, with *AquaBounty’s AquaAdvantage* genetically modified salmon, may be worried that the US Food and Drug Administration’s environmental assessment is unable to give either a complete or an accurate portrayal of all the risks and environmental and health harms involved, especially if wild salmon stocks become “contaminated.” Proponents who are

anti-genetically modified foods claim that no data set can, for that matter, account for the risks and uncertainties associated with this technology, since the likelihood of escapes and subsequent impacts on wild salmon stocks and human health cannot be adequately quantified by scientific measures alone.

Scientists may also encounter conditionally normative issues (Brunk et al. 1991, pp. 30–31) where judgments are appealed to in order to resolve the issue since data is momentarily unavailable. For example, “AquaAdvantage salmon is safe for the environment and for human consumption” may be premised (at the time) on a narrow adoption of the “probabilist” or “expected utility model” of risk (Thompson 1995), where risk is taken as a product of the “probability” or likelihood of a harmful outcome occurring and its magnitude (Friedman and Savage 1948). By circumscribing the magnitude of harm, for example, the FDA preemptively decided on the normative conditions that matter. The public feels that a rushed process has usurped their autonomous decision-making opportunity, they may be suspicious of experts who reduce risk to a utilitarian ethical basis. Those concerned about genetically modified foods and those who depend on “the wild caught label” or wild fisheries for their livelihoods, on the other hand, may see the matter as inherently normative if risk is conceived in terms of personal well-being (Plough and Krimsky 1987; Thompson and Dean 1996) and whether or not they feel hoodwinked or betrayed by the experts and the FDA.

Agricultural and food scientists must be in a position to comprehend fully the broader impacts of choices and decisions that they make based on assumptions, values, and preferences to which they are committed in the discharge of their professional responsibilities as scientists. They should also be cognizant about which of these ethical concerns takes priority over others in the public consciousness, and whether the burdens and benefits associated with either the results they infer or line of thinking they advocate (either intentionally or not) are equitably distributed among the relevant stakeholders. Cultivating certain professional virtues can go a long way in

promoting a trustworthy relationship with the lay public. Examples of these virtues include respect, honesty, openness, compassion, conscientiousness, integrity, and accountability. Alongside these virtues, professional rules, e.g., oaths to the professions and codes of ethics, can offer guidance to agricultural scientists and prompt them to understand their obligations to the public and their colleagues and what constitutes acceptable behavior.

Sources of Specific Ethical Concerns Related to Trust

The agricultural and food sciences must contend with both substantive and procedural ethical issues. Substantive issues are about philosophical and normative commitments associated with the moral status of particular matters such as the intrinsic or extrinsic ethical concerns of genetically modified food sources. Procedural issues are about the ethical governance and decision-making mechanisms that involve science, technology, policies, laws, regulations, and best practices.

On the substantive side, agricultural and food scientists must contend with ethical diversity. Ethical diversity can be instantiated in different ways and includes (adapted from Anthony 2012a):

1. Competing ethical frameworks
2. Contrasting duties to the commons
3. Varying conceptions of harm
4. Differing accounts of sustainability

On the procedural side, agricultural and food scientists may be steeped in discourses about the shape of their engagement with the public, producers, policy makers, and industry. A key challenge is to ensure that the discourse spaces promote engagement and trust through consultative knowledge transfer and laypublic and multidisciplinary involvement, collaboration, and empowerment (see, e.g., Burgess 2004). Thus, it is important that many relevant viewpoints are represented in order to produce a deliberative process that is robust and not “hijacked” by special interests. In policy making, scientists

need to show understanding for the difficult issues and sensitivity to different value systems, regardless of their personal viewpoint, and encourage transparency and honest brokerage of complex issues (see, e.g., Pielke 2007).

On the epistemological side, the agricultural sciences must be cognizant of the nuances associated with epistemically dependent relationships which can undermine public trust, such as knowledge deficits that can lead to information hierarchies of power and estrangement. The tendency to privilege facts over values and the temptation to relegate or trivialize values to the realm of the emotional or as knee-jerk responses may also plague science-public discourses (Felt et al. 2009). These issues are briefly considered below in turn:

Substantive Issues

1. Competing Ethical Frameworks

There is significant disagreement about how to understand the common good across many value and ethical systems. Those working in agriculture and food may be perplexed about “what is the right thing to do.” They may be influenced by religious and cultural principles. Appreciating a fuller range of ethical perspectives at the frontiers of food and agricultural sciences is essential to ensure equity and avoid tunnel vision. Here are but a few ethical approaches that pervade common morality:

Rights and duties, benefits and harms, and/or virtues and vices are part and parcel of common morality and impact ethical decision-making processes. They underscore how individuals evaluate the behavior of others as well as give guidance for their own habits. Briefly, a rights-based approach holds that moral subjects ought to be treated with dignity and they possess certain claims that cannot be “trumped” by consequences, no matter how good the outcome (see, e.g., Thompson 1998). Here, the morally obligatory or permissible action is the one which protects the moral interests of rights bearers. Proponents of this view may voice their disdain if certain

agricultural technologies or policies benefit a few on the backs of the least well off in society. A harm-benefit approach, on the other hand, reflects consequentialist thinking. On a standard account of this view, namely, utilitarianism, right action is that which produces the best possible balance of good consequences over bad consequences for all the relevant parties (see, e.g., Thompson 1998). Proponents of this view may ask if the utilitarian ethic that is the engine behind much of contemporary agriculture has unintended consequences (or can it genuinely promote a more sustainable model of resources use and management vis a vis “sustainable intensification”), such as devastation of rural communities and landscapes, biodiversity loss, soil erosion, water pollution, and human and animal health and welfare, and if so, how the harms-benefits associated with the successes of this ethic have been calculated. Virtue ethics, as a normative ethical theory, contends that right action is that which is consistent with the set of ideal qualities of character or dispositions that promote excellent people and/or good citizenship (see, e.g., Hursthouse 2006). The question “What sort of person/community should an individual or community aspire to be?” takes center stage. The theory involves what one (or a community) regards as worthwhile pursuing or preserving through food mores and agriculture with the view that the activity will contribute to human flourishing.

The interplay between rights, virtues, consequences, and other value systems may influence how agricultural and food scientists understand what is central to food security, for example. A utilitarian perspective may emphasize food security as availability of food, and thus, scientists committed to this approach will likely promote efficient production and abundance of food commodities at a low cost. A rights-based view may highlight cultural acceptability of food and ensure that the right to food, i.e., access, is premised on treating people with dignity and equity over cost or production efficiencies. A virtue’s view may emphasize the agency of people in

the food system and habits of character that promote sustainable communities through and with food and agriculture (Anthony 2012b).

2. Contrasting Duties to the Commons

The commons here refers to interests shared or resources held together within the public domain. Many contend that some portion of Earth’s natural resources (e.g., land, water, air) should be available to all people to carve out an existence in order to sustain themselves. Further, “know-how” in order to produce food and the opportunity to be self-reliant should also be accessible to the public without too many bureaucratic and corporate barriers. That is, human beings, when not causing harm to others, should be free to pursue the means to produce nutritious and safe food according to their value systems and should not be blocked by private enterprise or hindered by governments. Community or civic self-reliant agriculture can be seen as reflective of the US Land Grant mission. Garret Hardin (1968) warned against the depletion of shared resources by individuals (or private enterprises) acting independently and rationally according to their own self-interest at cost to others or society’s long-term best interest. Overfishing and overgrazing by monolithic commercial interests, for example, are forms of “enclosure” or monopoly that threaten this notion of the commons, especially when fertilizer or pesticide use, soil erosion and nutrient depletion, skyrocketing greenhouse gas emissions, and excessive waste produce dead zones that endanger human and animal communities just for immediate-term private gain (see, e.g., FAO 2012a, b).

Scientists can help the public and policy makers decide how to address competing duties and how to limit damage and manage the commons by means of governmental intervention and/or regulation by international bodies and how to protect against inimical exploitation of natural resources by private interests. They can also help to empower local communities by strengthening civic food networks and through knowledge transfer projects. Whether scientists and policy makers

encourage a more cooperative view as the best way to achieve a more sustainable agricultural commons in the long run or let the market decide will have implications for our environmental and natural resource capital (see, e.g., Parry et al. 2005; Tilman et al. 2011).

3. Varying Conceptions of Harm

The principle “Do No Harm” can be understood as being motivated by either the principle of non-maleficence or the principle of beneficence (see in Beauchamp and Childress 2008). In the former case, scientists may be motivated by the negative duty to (a) refrain from imposing greater harms than benefits to a population at risk, (b) avoid causing pain and suffering or death, or (c) end futile or non-fruitful strategies in order to meet certain agricultural challenges. Others committed to the principle of beneficence may be spurred on by the positive duty to relieve suffering, disease, or malnutrition and may focus on preventative or prophylactic measures. In both cases, scientists need to be sensitive to the different measures that might enter into their deliberations and the corroborating evidence that they take up. Weighing and weighting (i.e., how much weight is given to a particular outcome) will also determine how they consider the cost-benefit analysis as well whether or not they are committed to a decent minimum or threshold view of human well-being (see McMahan 1998). The cost benefit-analysis may take the form of utilitarianism, namely, to promote the greatest good for the greatest number or pareto optimality, that is, an action is permissible so long as what benefits the initiator of the action does not significantly harm others. Further, a more basic question is what agricultural and food scientists think about who can be the recipient of moral harm and benefit. Can animals or nature be the object of direct moral consideration, for example? The predominant view is that the “environmental commons” has no legal status other than in economic terms. It is often thought of as property, and thus land use for agricultural development and expansion for intensive purposes is often seen as progressive and preservation efforts as impractical and

obstructive, even inimical to human well-being. Careful calculations must be made in order to estimate the spatial and temporal dispersion of the impact of agricultural and resource development. Scientists and policy makers may not always be sensitive to how the benefits and burdens should be distributed intra- and cross-generationally and interspecifically and thus cannot ensure that they are distributed equitably. Further, they may not always appreciate how spaces and resources held as commons are valued passively for their recreational, aesthetic, or non-instrumental values. Hence, it is important that ethics be integrated into these discussions.

4. Differing Accounts of Sustainability

Currently, there appears to be a sociopolitical struggle around the normative dimensions of “sustainability” (Thompson 2010, p. 262). There are many views on sustainability that complicate how food and agricultural products are valued. Scientists should be open-minded when they assess, communicate, and manage concerns around sustainability since there are national, regional, and philosophical differences around this notion. The view of sustainability that is adopted has implications for the moral and epistemological outlooks and research agendas pursued (Thompson and Nardone 1999).

A dominant view of sustainability in discourses around food and agriculture revolves around resource sufficiency, where sustainability is “the rate at which resources are being consumed [over a time frame for which] the practice is to be sustained. If current or foreseeable supplies meet or exceed the calculated amount, the practice is sustainable” (Thompson 2010, p. 223). Resource sufficiency is concerned with the duration of availability of a given resource over a period of length. Exponents of this view of sustainability often rely on technology to fix their way out of challenges (Thompson and Nardone 1999).

Functional integrity, another popular conception of sustainability, is the capacity of a system to maintain itself without external disruption, centering on component aspects of an agri-ecological to regenerate (Thompson and

Nardone 1999). Exponents champion reproducibility and resilience of the whole system (Thompson 2010, p. 229). According to Thompson (2010), exponents of functional integrity rely on norms, values, and perceived obligations as inherent dimensions of agroecological systems.

Procedural Issues

Effective and responsible sites of public engagement are also central to promoting ethical trust between agricultural experts and the lay public. If the process of engagement with an informed public is undertaken as an open and honest process of inquiry (see, e.g., Dewey 1927; Hickman and Alexander 1998), then this will help to legitimize the ethical basis behind policy decisions. Public and multidisciplinary input at opportune moments can provide crucial evaluation of the relative merits of scientific claims and augment arguments that have a moral flavor and provide additional insights when scale and impact of risks associated with agricultural challenges are considered. When members of the public are actively more involved in the process of public policy making through engagement mechanisms that afford transparency and visibility, they are not only more confident that they have some semblance of control over how complex and controversial scientific issues are discussed, framed, and resolved, but there appears to be genuine opportunity for debate or dialogue concerning more basic questions over fundamental values or virtues related to the direction or shape of the enterprise (Felt et al. 2009). Appreciating the extent to which “facts” and “values” confound the engagement process is also central. By encouraging laypersons, policy makers, and scientists to equally commit to a process of mutual learning and to reflect on the pervasive bias that “Western science” fact is more authoritative over values (and are seemingly without social influence), policy makers may reduce hierarchical inequilibrium inherent in these relations. So as long as scientific knowledge is automatically accepted as superior to any value position and as

long as simple regulations become the foci for resolution to complex problems, some segment of the general public may have a hard time getting behind certain innovative and potentially fruitful policies (see, e.g., Pielke 2004).

Scientists who engage with the public must also guard against “downstreaming” (Felt et al. 2009, p. 362), a form of displacing ethical concerns to the margins or postponing important conversations about substantive issues that involve relegating public consultation to later stages of the policy innovation process. Downstreaming may weaken legitimacy and confidence in the outcome of a policy-making process and produce contempt for the sources of advice. Downstreaming can occur if the ethical is identified with the legal, for example. This maneuver actively forestalls the need for further debate and deliberation especially if the presence of existing regulation about a certain issue is taken (by those with decision-making authority) as a satisfactory terminal point. Participants who are fatigued by political apathy, or disenchanted by public discourses around food and agriculture may also defer their ethical jurisdiction and competency to so-called scientific or regulatory experts. Deflection of this sort of ethical responsibility to the regulatory space may mask the necessity of pursuing ethical inquiry into specific issues. When ethical questions are sidelined this way, laypersons may feel marginalized as a consequence of a lack of representation and opportunity to shape the trajectory of food and agricultural policies, especially in the wake of risks and impacts of novel technology on society (Haimes 2002). Proxy representation by self-proclaimed expert scientists and policy makers could fall short of what lay sources of knowledge may advise.

Epistemological Concerns

Members of the lay public may not be aware of all the nuances that apply to the science and technologies involved in food and fuel production. For example, how should public officials employ and manage water more efficiently for agricultural purposes and what technologies ought to be

applied in order to be more judicious about water and land use for agricultural production, both for plant- and animal-based systems? In some cases, given an untutored canvass of the available information, the lay public may be justified and rational in their initial estimations about specific issues (e.g., about the impact of genetically modified foods on their health) but may be inadequately informed, may be misinformed, or have false beliefs. While scientists and philosophers can help them to reason better, in many cases, the public may need help to digest and frame the relevant information and evidence in ways that enable them to rationally consider the evidence for what it is actually. It can be seen in instances of scientific and moral uncertainty, especially in the presence of conflicting “expert” testimony, knowledge deficits, and lack of awareness about agricultural and food issues. Since many members of the public do not have an independent understanding of the science and technologies that can be employed to resolve dilemmas and disputes, they are epistemically dependent on those in the know. They place trust in food and agricultural scientists to communicate impartial information about their work and the risks associated with agricultural products. A public that has a distrustful view toward “experts” may feel justified in discounting the evidential basis of the claims made by scientists who are perceived as coy, cagey, and not credible.

Scientists must be vigilant not to overestimate the value of the facts to which they appeal or arrogantly privilege only their own expertise. Facts or evidence-based claims are often the site of political struggle (Irwin 2006). Agricultural and food scientists should be aware that scientific evidence are also associated with values, preferences, and judgments and they can influence the ways in which the scientists pursue their research or the recommendations they make (Pielke 2007; Heymann et al. 2009). Furthermore, in instances where laypersons already feel subservient to the authority of “experts,” they may devalue their own empirical assessments (Felt et al. 2009). Here, there is a danger that ethics problems evaporate and are not considered when members of the public do not have confidence that their evidence

counts as the “right facts”. This is an example of ethical disenfranchisement. Which facts are employed and dismissed will impact the identification of what issues should be raised and how they ought to be framed and addressed. Furthermore, there is a danger of dismissing other sources of knowledge, for example, indigenous and place-based knowledge as inferior, untutored, irrelevant, or emotional. The epistemic asymmetry between facts and values remains sharp, where facts are taken as “givens,” but values are “constructed” or “merely one’s opinion,” or trivially characterized as “emotional.” Thus, in theory, there is a bias toward evidence-based claims as being stronger than value-based lay knowledge. However, the “fact-value divide” may have less force in reality at the end of the day. Which “facts” matter and why (e.g., how values are placed and displaced) depends less on there being a hard line separating facts from values but on social influences like outcomes and priorities set by communities with influence.

Summary

Agriculture continues to play a major role in the economic, social, and ethical activities of many communities in developed nations and emerging economies around the world. Apart from feeding people and providing jobs, agriculture, as a source of bioeconomy, is the vital lifeblood for many individuals and communities. Agriculture contributes to food stability and security and to the health and prosperity of both urban and rural communities.

Ethics, especially ethical trust, is the lynch pin that holds together the nexus of agents and elements that make up the global food and agricultural system. Since agricultural and food sciences are highly specialized and layered, consumers and citizens must defer to the good will and expertise of the cadre of scientists to “mind the store.” Trust in the scientific community is central since many of the developments necessary to meet the challenges mentioned above are public goods and will require a strong public commitment (in the absence of private inclination or commercial interests), to make ethically measured investments in

agricultural research, innovation, and technology development. Successful partnerships between the private and public sectors are crucial in identifying priority areas for research and development, managing risks, and appreciating the practical and ethical concerns faced by different communities around food and agricultural issues. When concerns cannot be met through public-private partnerships, public support is essential to pursue research outcomes that promote a more resilient, sustainable agricultural and food system whose benefits may be shared equitably by all.

Public consultation with respect to the ethical consequences or application of policy should be encouraged in earlier stages of the policy innovation process (Wilsdon and Willis 2004). Earlier engagement with a diverse lay public is central to help them appreciate the moral and epistemological issues at stake and to come to terms with policy and technical solutions. Scientists can help to link seemingly unrelated constituents in the food system to solve problems of food supply, processing, distribution, and use. Emergent collaborations that reflect a participatory decision-making process by a plurality of stakeholders can also promote the interest of the most vulnerable members of society if their advice is directly sought whenever possible to find innovative solutions for the challenges mentioned about and to build truly equitable, healthy and sustainable food and agricultural systems.

Introduction

Ethical concerns about the right to food and agricultural development are evident in debates within various United Nations (UN) agencies or associated international organizations (IO) and many agreements, commissions, working groups, and programs that those IOs implement or facilitate. Values conflicts and consensus have appeared in negotiated agreements leading to numerous founding charters and technical

treaties, reflecting diverse notions, objectives, and applications of fairness, justice, accountability, and responsibility. Ethical assumptions, tensions, and compromises are embedded in various standards, guidelines, principles, and indicators for defining, measuring, and effectively ensuring adequate, safe, nutritious, and culturally appropriate food, food rights, and agricultural development. Ethical issues have related to seed propagation, food growing, cultivation and processing methods, trade in food products, livestock production, horticulture, herding, fishing or aquaculture, pastoralism, plant gathering, agroforestry, and more. Interconnected ethical and rights concerns across UN agencies and other IOs have overlapped with discussions about access to and control over food, genetic resources, seeds, land, water, cultural heritage, and indigenous knowledge protection.

These and other ethical issues concerning food security, food rights, and agricultural development addressed by the UN or other IOs are referred to in academic literatures discussing food and agricultural ethics, environmental ethics, and development ethics; human rights and agricultural law; and in various UN, civil society, legal and farmer analyses or interpretation guides, and other primary documents. This entry reviews relevant debates, documentation, and reference materials historically and how these themes have evolved in contemporary contexts.

1930s–1980s: Early History of Food Rights, Safety, and Ethical Trade

Various notions of moral duty for wealthier, more privileged nations toward suffering or poorer peoples and countries were embedded in early twentieth-century global politics and IOs. That duty, sometimes based on even older or traditional cultural beliefs, as well as modern Christian or other religious, cultural, philosophical, and humanistic values, becomes translated into secular concepts about political, economic, or social justice. Those in some cases were transformed into specific legal commitments or obligations of governments with shared global diplomatic norms

in our modern international (Westphalian) system based on sovereign nation states. However, such ideas were never pure moral goals or legal strategies. They were always mixed with competing ideological, geopolitical, and socioeconomic objectives of governments as well as differences within or among their different ministries or agencies, including those people appointed to negotiate with, or who work in, IOs as diplomats or public servants.

Incipient policy ideas, legislation, projects, and program proposals linking ethical responsibilities of more fortunate countries to address the health, food, and nutritional needs of others, as well as economic or geopolitical interests of some countries to ensure open trade and increased consumption of agricultural products, were evident in discussions as early as the 1930s in the now defunct League of Nations (O'Brien 2000).

During the Second World War, planning for the new postwar UN reflected more urgently and widely shared moral values but also conflicting perspectives. They reflected geopolitical tensions and national interests of the soon to be victorious Western Allied powers that created the UN system which exists today and various international agreements, development programs, and agencies which contributed to or followed from its birth. The Food and Agriculture Organization (FAO) of the new UN was conceived in 1943 during war, as a post-war technical agency focused on food security. The United States hosted the FAO's first planning meeting with a vision built partly on a basic moral objective, "freedom from want of food," an aspect of the democratic justice vision and political, security, and moral values embedded in President Roosevelt's classic 1941 "four freedoms speech." The new FAO, established in 1945, was the first technical agency in a new UN system built on stated moral objectives as well as socioeconomic or perhaps even "distributive justice" aims (Macer et al. 2003, p. 482). Its 1945 Constitution affirmed that all nations joining would "...promote the common welfare... (while) contributing towards an expanding world economy and ensuring humanity's freedom from hunger..."

FAO's founding ethical vision and operational mandate had no explicit human rights objectives,

but the 1948 *Universal Declaration on Human Rights* gave the FAO and other IOs a clearer moral as well as legal compass. The 1948 Declaration pledged that: "Everyone has the right to a standard of living adequate for the health and well-being of himself and of his family, including food. . ." (Article 25). Later agreements, such as the 1966 United Nations *International Covenant on Economic Social and Cultural Rights*, enshrined more specific (albeit still vague) agricultural development and food security rights. However, governments did not easily meet such food rights obligations, or sometimes for sensitive political, religious, cultural, economic, or other reasons even intentionally avoided them. Instead, new IOs or programs, often championed and hosted by a particular government with its own unique ethical views, had to address specific concerns (including ethical tools or guides) for ensuring different kinds of food or agriculture rights. New IOs or programs partly addressed tensions, conflicting claims, and weaknesses of human rights law concerning food or agriculture by facilitating ethically significant codes of conduct, guidelines, standards, and principles.

In 1961, an International Convention established the International Union for the Protection of New Varieties of Plants (UPOV) as an IO to encourage plant breeding by granting breeders intellectual property rights for new plant varieties. Its mandate aimed to encourage and safeguard breeders' interests while serving national agriculture development. The UPOV resulted in some major ethical debates and practical, legal challenges between opposing sets of rights, those of breeders and farmers. For example, farmers could be breeders but still have their traditional agricultural knowledge or germplasm exploited by scientist breeders, governments, and private corporations and may not have their own varieties recognized or protected.

During the early 1960s, ethical concerns also emerged surrounding the international trade and consumption of safe food. The FAO and World Health Organization (WHO) formed the Codex Alimentarius Commission (CAC) in 1963 to develop food standards, guidelines, and texts such as codes of practice under the Joint

FAO/WHO Food Standards Program. The CAC, which continues its work today, set out to develop standards for particular types of foods, commodities, or industries based ostensibly on scientific or objective rationale for ethical codes and guidelines. Its work has covered a range of measures related to food additives, pesticide residues, nutrition levels, contaminants, hygiene, food labelling, and more.

In the 1970s, government and public consumer concern grew over the emerging power and some unscrupulous behavior of the food and agriculture industry in addition to worries about unsafe food. The FAO/WHO Program and CAC produced a *Code of Ethics for International Trade in Food Including Concessional and Food Aid Transactions*, adopted first in 1979, revised in 1985, and again in 2010. Its major objective was to establish principles for the ethical conduct of international trade in food, to protect the health of the consumers, protect import countries from dumping, and ensure fair food trade practices. But Codex work has still been contentious over competing values, allegations of inappropriate corporate industrial influence, technical disputes over what should be deemed safe, and different definitions of ethical trade. This Code was (and still is) a voluntary mechanism to encourage (not legally insure) food safety standards by companies and governments while not inhibiting international trade. An ideology (or for some an ethical value) of free trade market "fairness" partly competes with food product safety considerations in the Code.

The FAO in 1983 established a *Commission on Genetic Resources for Food and Agriculture (CGRFA)* to develop international policies and agreements related to management of plant genetic resources as well as farmers' rights. Initial UPOV work (noted above) to protect breeders' rights had conflicted with farmers' concerns and broader ethical considerations of competing rights claims. A 1989 FAO Conference partly reconciled this conflict adopting two resolutions (*Resolution 4/89, Agreed Interpretation of the International Undertaking*, and *Resolution 5/89, Farmers' Rights*) aiming to balance

breeders' and farmers' rights. One major ethical issue ostensibly resolved was affirming a principle of greater respect for farmers' values, traditions, and knowledge. Other serious ethical concerns soon emerged over Intellectual Property Rights (IPRs), especially claimed by corporations, partly resolved in legal terms (yet without well addressing important ethical concerns) under the Agreement on Trade-Related Aspects of Intellectual Property Rights (known as TRIPS) in 1986, which came into effect in 1996 under the new World Trade Organization (WTO). Yet how best to interpret and apply farmers' and breeders' rights, as well as indigenous peoples rights (who may also be farmers) in human rights law and in trade, has remained ethically contentious, legally confusing, and politically debated and remains open to conflicting interpretations (Andersen 2005; Moore and Tymowski 2005; Oguamanam 2006). IPRs and TRIPS remain contentious now despite ostensibly greater legal protection for farmers and indigenous rights in principle.

1990s–2000: Sustainability, Agricultural Biotechnology, Genetic Safety, and Bioethics

The 1990s began as the Cold War ended. But other debates or concerns relevant to sustainability, food, and agricultural development ethics followed with major implications that some IOs, particularly UNESCO and then FAO, were to explore more strategically and systematically. With guidance from the FAO, the CGRFA, and other agencies or commissions, new IOs or programs were launched to coordinate more effective responses to ethical as well as practical challenges for conceptualizing sustainable agriculture and achieving food security.

The 1992 Rio Declaration on Environment and Development and the United Nations Conference on Environment and Development (UNCED) agreed by most world leaders reflected shared ethical assumptions or values or principles intended to shape a common (sustainable) future. Principle 15 of the Declaration building on some earlier

academic and UN deliberations affirmed the value of “the precautionary approach” stressing that “where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation.” This “precautionary principle” was one of UNCED’s key ethical guiding notions for future environmental (and food or agricultural) decision-making, although it has remained a contentious idea, continuously debated for its moral, policy, and practical implications, especially related to assessing environmental as well as legal risks associated with genetically modified (GM) seeds, plants, or food among other issues. UNCED’s *Agenda 21* vision offered tools, mechanisms, and targets. *Chapter 31* referred to “Scientific and Technological Community” responsibilities to develop codes of practice or guidelines regarding environmentally sound and sustainable development and “. . . establish advisory groups on environmental and developmental ethics. . . to develop a common value framework. . .” Other Chapters discussed “sustainable agriculture,” farmers, and more, implicating IOs’ follow-up.

UNCED planning coincided with negotiations for the 1992 *Convention on Biological Diversity* (CBD) and a new IO, the Secretariat of the Convention on Biological Diversity (SCBD). The CBD posed a major ethical challenge, that is, “the conservation of biological diversity, the sustainable use of its components and the fair and equitable sharing of the benefits arising out of the utilization of genetic resources, including by appropriate access to genetic resources and by appropriate transfer of relevant technologies, taking into account all rights over those resources and to technologies. . .” (Article 1, Objectives). What can be considered “fair” or “equitable” and whose rights to consider was (and still is) a major ethical and legal concern. Contentious technical debates and political negotiations have been in the CBD language of “access to genetic resources and benefit-sharing” (ABS) with competing rights claims, ethical arguments about sharing and access, as well as improved standards for trade, and stated (but still conflicting) needs of researchers, governments, industry, farmers, and

indigenous peoples (Moore and Tymowski 2005; Greiber et al. 2012).

Other IO processes also recognized serious ethical concerns associated with the rapidly emerging field of biotechnology research. In 1991, the CGRFA in consultation with over 400 international experts from the scientific community and civil society prepared a *draft Code of Conduct on Biotechnology*, to maximize its positive effects and minimize possible negative effects. In 1993, the FAO through the CGRFA recommended that the biosafety component of the draft Code be forwarded to the CBD to be considered for its Biosafety Protocol then under negotiation. The CBD approved the *Cartagena Protocol on Biosafety to the Convention on Biological Diversity* in 2000. That technical agreement aimed (among other things) to ensure safe handling, transport, and use of living modified organisms (LMOs) resulting from biotechnology. The Protocol did not, however, fully resolve many larger ethical issues associated with agricultural biotechnology.

In this same period, the Consultative Group on International Agricultural Research (CGIAR), in 1997, already involved with FAO, CGRFA, CBD, and other IOs or processes reflected on how ethical principles could strengthen its own mission. The CGIAR, a quasi-UN agency established in 1971 to promote agricultural sciences for development and poverty reduction among developing nations, today consists of 15 specialized centers working in over 100 countries. The CGIAR has partnered with other IOs to protect agricultural biodiversity and native varieties through gene banks, in situ conservation, crop research, and training. Its 1997 draft *Ethical Principles Relating to Genetic Resources* referred to four principles: equity; trusteeship of genetic resources; respect, responsibility, and integrity in science; and social benefits encouraging individual centers to elaborate with respect to their particular mandates.

The CBD after 1995 gradually broadened its mandate demonstrating biodiversity's relevance to food and agriculture. By 2000, the CBD launched a new work program on agricultural biodiversity for its "conservation and sustainable use." This was another contentious ethical

concern as private corporations accused of "bio-piracy" sought to assert rights to commercial exploitation of (and at times exclusive patenting of) genetic resources under the CBD and its ABS provisions or through other IO mechanisms such as the CAC, TRIPS, CGIAR, and WTO.

Further complementing (and complicating) CBD's work, the FAO, with the CGRFA (noted above), worried about loss of genetic resources as a whole, with many species or varieties under threat yet important for future agriculture development and food security. The CGRFA wanted to conserve those resources with local people's rights in the context of national sovereignty. For those purposes, the CGRFA in 1993 adopted a nonlegally binding *International Code of Conduct for Plant Germplasm Collecting and Transfer*. But ethical concerns continued over different interpretations of human or indigenous rights claims to nature or genes conflicting with corporate IPRs within the CGRFA Code, CBD, TRIPS, CGIAR, and other mechanisms.

During the 1990s, some science and technology issues became even more publicly contentious. In response, the Educational, Scientific and Cultural Organization (UNESCO), in 1993 launched an International Bioethics Committee (IBC) and created a new bioethics program, initially working on human genome issues, but later addressing plant genetics with food and agriculture. In 1998, UNESCO established the *World Commission on the Ethics of Scientific Knowledge and Technology (COMEST)* as an advisory body to address broader concerns (ten Have 2006, p. 336).

Toward the end of the 1990s, many ethical challenges posed by rapid advances in science and society more clearly and urgently implicated food and agriculture. The FAO commissioned a related study of FAO staff views. That review, based on 103 interviews, indicated that although ethics had not been openly discussed much until then most staff members had strong ethical motivations. FAO staff perspectives covered a range of broad ethical issues (food, rural development, information, biotechnology, sponsorship/funding, environment, animals, and personnel) including many more specific subthemes (Bhardwaj et al. 2003).

2000–2008: Ethical BioTrade, Water, Corporate Accountability, and Food Rights

As the new century began, many interrelated ethical challenges affecting food security, agriculture, and human rights persisted, intensified, grew, diversified, and became more complex but were still poorly debated or analyzed in public discourse or IO policies and programs. However, after 2000 some IOs began to more systematically (through dedicated new programs and budgets) address some of those issues. They began a more critical examination of the ethics of emerging technologies applied to food and agriculture; how to best realize food rights; began to focus more strategically on water and climate change issues (some affecting food and agriculture); and initiated a dialogue about ethical guidelines for corporate industrial behavior affecting agri-food businesses.

Among the principal IOs or special new initiatives implicating food security and agricultural development ethics were the FAO and UNESCO (introduced above) and new IOs or offices including the UN Global Compact (UNGC) and the UN Special Rapporteur on the Right to Food, both beginning work in 2000.

The United Nations Conference on Trade and Development (UNCTAD) which had been founded in the 1960s to better represent the economic, trade, and investment interests of the poorer, and then politically marginalized developing countries, made a small contribution to ethical trade guidelines affecting food and agriculture products among other sectors.

UNCTAD's new work focused on trade issues related to the CBD and other international initiatives. This resulted in new *BioTrade Principles and Criteria* in 2007, which included Criterion 2.2 stressing that "management of agro-biodiversity should include agricultural practices that contribute to the conservation of biological diversity" and "create conditions that favour the regeneration of natural ecosystems." Criterion 4.4 further underscored that "Negative impacts on, *inter alia*, productive and local cultural practices

that affect diversification and food security should be prevented" (UNCTAD 2007).

UNCTAD also provides guidance by serving on the board of a related new NGO called the Union for Ethical BioTrade (UEBT) established in 2007. The UEBT has focused on further developing related concepts and principles, with more specific technical standards and verification frameworks. These have all built on UNCTAD's seven *BioTrade Principles and Criteria*, namely, (i) conservation of biodiversity, (ii) sustainable use of biodiversity, (iii) fair and equitable sharing of benefits, (iv) socioeconomic criteria, (v) compliance with national and international regulations, (vi) respect for the rights of actors involved in BioTrade activities, and (vii) clarity about land tenure, use, and access to natural resources and knowledge. Agriculture, as well as aquaculture, sourcing, harvesting, production, processing, value chains, market development, and food trade, cuts across all of these principles. UNCTAD's most recent work further offered specific guidelines for assessing BioTrade resources based on biological as well as socioeconomic studies (UNCTAD 2013).

New attention in this period also focused specifically on transnational corporations (TNCs) including discussions of agribusiness. One UN Commission on Human Rights report in 2003, for example, on *Norms on the Responsibilities of Transnational Corporations and Other Business Enterprises with Regard to Human Rights* mentioned TNC obligations toward the realization of the right to adequate food. Among the new UN initiatives have been strategies to improve corporate social responsibility (CSR). The UNGC articulated "ten principles for a better world," which support human rights, labor standards, environmental protection, and (more recently) anti-corruption, for those businesses which signed on to the Compact.

However, critics of the UNGC and many other CSR initiatives, which benefit from the UN image, affiliation, or guiding principles, have suggested essentially that this type of CSR focuses on ideas of "responsibility" and voluntarism in codes of conduct or guidelines while it advances positive corporate images but avoids

corporate “accountability.” The UNGC, they argue, has not provided any clear monitoring or enforcement mechanisms (Corporate Watch 2006, p. 8). One UN study historically documented this issue, highlighting similar concerns with brief reference to food corporations (Bendell 2004).

UNESCO after 2000 also identified major ethical issues, analyzed policy implications, made additional program recommendations, conducted ethics education activities, prepared learning resources, and facilitated new international agreements. In 2002, it made ethics one of five priority areas under its Social and Human Sciences Program. One initial result was UNESCO’s 2005 *Universal Declaration on Bioethics and Human Rights*, which under Article 17, referred to “. . . the role of human beings in the protection of the environment, the biosphere and biodiversity.” A major ethical implication of that agreement among UNESCO member states is that “the world’s major food crops depend on new genetic material from the wild to remain productive. . .” (ten Have and Jean 2009, p. 251). This UNESCO Declaration complements others including the International Treaty on Plant Genetic Resources for Food and Agriculture (ITPGRFA) in 2001 and the 1994 TRIPS Agreement.

UNESCO, in the new century, also began more focused work on various other ethical issues associated with biodiversity, water, and climate change. As early as 2000, UNESCO’s COMEST was working on water ethics. One report focused on freshwater consumption and use referring to agriculture and food security implications while offering suggested ethically based guidelines. It said food security was a “moral imperative” and that “more efficient use of water for agriculture should be encouraged to increase soil production and crop yield and to avoid waterlogging and salinization” (Selbourne 2000, pp. 11–13, 38).

In 2007, UNESCO’s *International Hydrological Program* with support from its *Division of Water Sciences* with others co-organized an *International Conference on Water, Ethics and Religion* in Stockholm and a workshop in Spain while engaging other UN agencies. Those meetings discussed, among other issues, ethics of virtual water in food trade, as well as broader food

security, food production, and governance concerns. The meeting and research report involved experts from the United Nations University (UNU) and International Water Management Institute (IWMI), a Colombo-based CGIAR center working on interrelated water, environment, and food issues (Llamas et al. 2007, pp. 81–96, 171–186).

For UNESCO, the Asia Pacific region was one of the most active in establishing new networks, hosting conferences, and producing publications on ethical issues some including references to food and agriculture ethics. One, for example, in 2010 as its title suggests, wrestled with the issue of *Universalism and Ethical Values for the Environment* as part of a new UNESCO “Ethics and Climate Change in Asia and the Pacific (ECCAP) Project” (Rai et al. 2010). Another, the following year, entitled *Ethics and Biodiversity*, included analyses concerning biodiversity and food production, food safety, food webs, water, climate change with concern over rights claims and food security, as well as special reference to Asian contexts and cases (Macer 2011). Several other working groups and UNESCO meetings as part of this work addressed related ethical issues.

The FAO after 2000 formally designated ethics a new priority for interdisciplinary action partly in response to expanding TNC influences among other factors. It established a new Committee on Ethics and an independent Panel of Eminent Experts to review critical issues and inform decision-making. The FAO over the next several years held consultations on particular ethical issues, conducted studies, and issued a series of reports. They included a broad overview: (1) *Ethical Issues in Food and Agriculture*, 2001; (2) *Genetically Modified Organisms, Consumers, Food Safety and the Environment*, 2001; (3) *Expert Consultation on Food Safety: Science and Ethics*, 2002; and (4) *The Ethics of Sustainable Agricultural Intensification*, 2004. Those reports, addressing many issues FAO staff earlier identified, including more recent concerns, such as such as biofuels, articulated various ethical challenges and dilemmas while offering some technical analysis of specific issues with recommendations for policy-makers.

After 2000, some IO work more explicitly linked human rights, food security, and agriculture with ethics, drafting or calling for related guidelines, particularly with concern over the growing role of TNCs which arguably have ethical, if not legal, responsibilities to contribute to the realization of the “right to adequate food.” The *UN Special Rapporteur on the Right to Food* at the time asserted that their global reach was “not matched by a coherent global system of accountability” and that “despite wielding greater power than ever before” TNCs were “trying to avoid being held accountable...” (Ziegler 2006, pp. 16–18). The FAO began facilitating consultations and reports on ethical issues with practical accountability tools for TNCs and others. This resulted first in the 2004 *Voluntary Guidelines to Support the Progressive Realization of the Right to Adequate Food in the Context of National Food Security*.

The CGIAR in this same period began reflecting more seriously on ethical questions in response to internal reviews as well as public criticism of its biotechnology work. In a 2007 *Report of the Biosafety Panel to the CGIAR Science Council on Biosafety Policy and Practices of the CGIAR Centers*, the CGIAR suggested much debate had been about the perceived morality of transgenic technology, but that its concern was “practical ethics,” or learning from and adopting “best practice.” The CGIAR did not question the moral value of transgenics research, which it had been increasingly engaged in and planned to continue. It instead focused on “safety” issues and protocols. Nonetheless, the CGIAR’s first major ethical review in 2008 acknowledged it had poorly analyzed or responded to many “sustainability” or “protecting nature” concerns and that budget pressures could undermine an ethical vision (CGIAR Science Council 2008, p. 86; and discussed in Nelles 2011, p. 412).

Finally, one other IO after 2000, the United Nations Environment Program (UNEP), which had partnered with UNESCO since the mid-1970s on joint environmental education (EE) activities, made a small contribution under its EE unit programming to environmental ethics education. UNEP produced a guidebook with

illustrations referring to food security and agriculture challenges among many others (Jickling et al. 2006, passim; UNESCO n.d.).

2008 to Present: Agrobiodiversity Protection, Land Grabs, Responsible Investment, Climate Crisis, Environmental Change, and Sustainable Agriculture

Interconnected global financial, fuel, and food security crises during 2008 and 2009, with food riots over prices, hunger, and access, led to protests worldwide among farmers, consumers, and civil society groups (Holt-Gimenez et al. 2009). Such deepening and widening problems contributed to ongoing and new ethical considerations. Climate change concerns with ethical debates about some responses, such as biofuels competing with food security and ecological objectives, also created new, more complex dilemmas for IOs and led to new debates and initiatives. Governments and TNCs seeking new food sources and profit-making opportunities including new land acquisitions brought new ethical debates amid CSR ideas, corporate accountability, and the need for better guidelines for business and investment that would still insure farmers’ and broader human rights. New IO initiatives followed.

By this time initial CBD negotiations led in 2010 to the *Nagoya Protocol on Access to Genetic Resources and the Fair and Equitable Sharing of Benefits Arising from their Utilization to the Convention on Biological Diversity*. It included a new responsibility commitment on how best to conserve and protect agrobiodiversity. UNEP also made a small contribution to related debates in partnership with a university-based ethics center. It published a related ethics report which pointed out that the CBD, which also was concerned with the importance of biodiversity for food security and sustainability of the world’s food supplies, did not define the meaning of equity and fairness (Schroeder and Pisupati 2010, pp. 9, 19). The UNEP study included analysis of human rights and benefit-sharing issues surrounding the ITPGRFA and other themes.

Ethical issues over agricultural biotechnology, relations among scientists and small farmers, and IPRs intensified as CGIAR partnerships increased with private sector companies, foundations, and government donors' influence over research priorities. After the complete restructuring of the CGIAR in 2009–2010, it newly addressed ethical issues in 2012, adopting *CGIAR Principles on the Management of Intellectual Assets* (known as “*CGIAR IA Principles*”) implying it had a responsibility to share its research results as a “public good” while strengthening national research systems to combat poverty among the poorest while promoting sustainable development. The referential, interpretative context for *IA Principles* implementation was various legal agreements, treaties, protocols, and processes and human rights instruments including the CBD, Nagoya Protocol, UPOV Conventions, and others.

Also in 2012, the FAO helped conclude both *Voluntary Guidelines on the Responsible Governance of Tenure of Land, Fisheries and Forests in the Context of National Food Security* and *FAO Guiding Principles for Responsible Contract Farming Operations*. One major related review facilitated by the UN Committee on World Food Security (CFS) has also been *Principles for Responsible Agricultural Investments* (PRAI) Zero Draft, to be finalized in 2014 as stakeholder consultations continue. That work built on FAO collaboration with the International Fund for Agricultural Development (IFAD), UNCTAD, and the World Bank (see IFAD, the UNCTAD Secretariat, and the World Bank Group 2010). The PRAI draft focuses on eight main principles to improve or strengthen “responsible investments in agriculture and food systems” including reference to food security and nutrition and the progressive realization of the right to adequate food... (Principle 1); economic and social issues (Principle 2); environment, natural resources, and climate change (Principle 3); cultural issues (Principle 4); policy coherence and sector development (Principle 5); governance, grievance mechanisms, and accountability (Principles 6 and 7); and review mechanisms and accountability (Principle 8). Numerous other agreements, codes, and processes underpin or link to the

proposed PRAI (Committee on World Food Security 2013). Still other IO initiatives and related CSO or business led activities complement CFS and PRAI work (Committee on World Food Security 2013).

The CFS after 2009 when it underwent reform (partly in response to the 2008 food, financial, fuel, and emerging climate crises) has been one of the more innovative, civil society responsive mechanisms of the UN system, including family farmers, fisherfolks, herders, landless, urban poor, agricultural and food workers, women, youth, consumers, and indigenous people. But although various groups have engaged in PRAI negotiations, some, including Via Campesina, GRAIN, and other key civil society networks and farmer movement organizations, criticized the PRAI concept, assumptions, and ethical foundations. They suggest the FAO should prevent land grab abuses, yet through the PRAI it (unethically) legitimizes farmland grabbing by corporate and state investors. Fundamentally, as they note, the PRAI and similar instruments are all *voluntary* guidelines (i.e., suggestions), not legally enforceable food rights or farmer rights (i.e., to protect land or biodiversity, produce food, save seeds, etc.). Some civil society and farmer rights critiques center around this overarching ethical issue as well as the basic, institutionalized problem of a TNC-dominated global agribusiness and food system supported by governments. They demand justice against rights abuses and support for alternative (agroecological, small farmer based) systems (GRAIN 2012; Holt-Gimenez et al. 2009).

Reflecting similar concerns with respect to some overlapping or broad ethical issues identified or implicating the FAO, WHO, Codex, CBD, CGRFA, UNESCO, CGIAR, and WTO, a FAO Expert's Commission on Ethics argued that core ethical issues in food and agriculture arising from the TRIPS, for example, were then still unresolved and pressing. Those issues were:

- The increasing risk of a transfer of important knowledge from the common domain (public goods) to the private domain, often controlled by corporations

- The likely negative impact of the TRIPS Agreement on the livelihood of poor farmers
- The uncertain impact on sustainable access to affordable, safe, nutritious food for consumers with limited income
- The environmental impact, including the effect on biodiversity (Food and Agriculture Organization of the United Nations 2011, p. 32)

Finally, also under UNSG auspices and administrative coordination of the Sustainable Agriculture Team of the UN Global Compact (UNGC), the UN is currently developing the Sustainable Agriculture Business Principles (SABPs) in consultation with a “Core Advisory Group” (CAG) of various business, civil society, NGOs, experts and academics, commodity roundtables, as well as other UN agencies. The UNGC’s initial *white paper* identified six “frames” for SABPs based on the following ideas: (1) be environmentally responsible; (2) ensure economic viability and share value; (3) respect human rights, create decent work and help rural communities to thrive; (4) encourage good governance and accountability; (5) improve access to and transfer of knowledge, skills, and technology; and (6) aim for food security, health, and nutrition. It further suggests drawing from “Principles for Responsible Engagement” adapted from a November 2010 guide related to business and water policy. A final agreement on SABPs is expected sometime in 2014 (UN Global Compact 2013).

Over the past decade, but especially since the interconnected food, financial, and fuel crisis of 2009–2009, global environmental problems have also intensified and become more difficult to curtail or mitigate. They include: land degradation, deforestation, desertification, pollution, aquifer depletions, greenhouse gas emissions and climate change, habitat and biodiversity loss, GMO contamination/pollution, and more. A recent FAO experts’ review summarized some of these and the ethical response needed as “essentially twofold.” The first is to promote conditions to ensure access to adequate food. The second is to promote policies and measures ensuring ecological sustainability of food production (FAO 2011, p. 10).

These two main ethical concerns – food rights and ecological sustainability – will likely remain central to current public debates, unresolved science and policy conflicts, and related IO initiatives in the future.

Summary

Ethical debates and proposed norms or guides, some linked to food rights and security discourse, have been part of food and agriculture within UN system and affiliated IOs since their early foundations in the 1940s. Beginning in the 1960s and 1970s, food safety and quality issues grew with ethical concerns among existing or new IOs and agreements. From the 1980s environmental issues and sustainable agriculture concepts informed ethical debates as well as new codes of conduct in food and agriculture. After 2000, the increasing power of TNCs involved in food and agriculture, greater environmental awareness, and human rights concerns, as well as criticism from civil society and farmer groups, leading to new investment codes and principles, some still under negotiation. Yet many ethical debates remain inadequately addressed by IOs today. Unresolved concerns still surround questions of TNC accountability and if “ethical” only approaches (i.e., principles, standards, voluntary codes, etc.) will be sufficient to insure environmental sustainability and food security rights or support ecologically sustainable agricultural development that will further adequate and dignified livelihoods for small farmers.

Glossary of IO Terms/Acronyms

ABS	Access to Genetic Resources and Benefit-Sharing
CAC	Codex Alimentarius Commission
CBD	Convention on Biological Diversity
CFS	Committee on World Food Security
CGIAR	Consultative Group on International Agricultural Research
CGRFA	Commission on Genetic Resources for Food and Agriculture
CHR	Commission on Human Rights

COMEST	World Commission on the Ethics of Scientific Knowledge and Technology
CSM	Civil Society Mechanism (CSM), Working Group on Investment of the CFS
CSR	Corporate Social Responsibility
FAO	Food and Agriculture Organization of the United Nations
IBC	International Bioethics Committee
IPRs	Intellectual Property Rights
ITPGRFA	International Treaty on Plant Genetic Resources for Food and Agriculture
OECD	Organisation for Economic Co-operation and Development
PRAI	Principles for Responsible Agricultural Investment
SABPs	Sustainable Agriculture Business Principles
SCBD	Secretariat of the Convention on Biological Diversity
TRIPS	Trade-Related Aspects of Intellectual Property Rights
UEBT	Union for Ethical BioTrade
UNCED	United Nations Conference on Environment and Development
UNCTAD	United Nations Conference on Trade and Development
UNESCO	United Nations Educational, Scientific and Cultural Organization
UNGC	United Nations Global Compact
UPOV	International Union for the Protection of New Varieties of Plants
WHO	World Health Organization
WTO	World Trade Organization

[Decision-making framework](#); [Dietitians](#); [Ethics](#); [Food](#); [Medicalization](#); [Nutrition](#)

Introduction

Registered dietitians are those charged with addressing nutritional health in clinical, public

health, and private environments as well as overseeing the production of large-scale food operations in hospitals and other organizations. Given the ethical debates surfacing within contemporary food and nutrition topics, dietitians are often in positions where ethical decisions are required. However, ethics as an area of inquiry within dietetics is limited. Furthermore, there is a paucity of evidence that ethics is taught to dietetic students during their undergraduate education. This situates dietitians as having to address ethical issues while being largely unprepared to do so. The purpose of this essay is to outline ethical debates in dietetics and propose a means to adequately prepare food and nutrition professionals for ethical decision-making frameworks arising in practice. Additionally, areas of further inquiry into ethics within the context of dietetic education and practice will be outlined.

Dietetics as a Profession

A hallmark of the dietetic profession is that it emerged from home economics in the 1970s. Increasing determination to medicalize nutrition and remove the work of dietetics from the home and place it more squarely in the public realm underscored this period in the profession's historical development. Along with this move came the growing importance of the dietetic professional association that marketed dietitians as trusted authorities on nutrition and food. In doing so, the association made clear that dietetics was an exclusive profession to which entry was only granted by completing a 4-year university degree and a 1-year practical internship completed typically in a clinical setting. Simultaneously, the associations developed codes of ethics to guide dietetic practice.

Codes of Ethics in Dietetics

Dietitians of UK, the Academy of Nutrition and Dietetics (USA), the Dietitians Association of Australia, and Dietitians of Canada have all provided their codes of ethics for public viewing online. Although these national codes exist, their

enforcement varies. In Canada, for example, the regulation of dietetic practice is a provincial matter, thus leaving the national association's code of ethics unenforceable. The ten provincial regulatory bodies have provided distinct but not dissimilar codes for dietetic practice that apply to members in each province. If there is an ethical violation, the provincial regulatory body has jurisdiction to address that violation. According to representatives at each nation's association, reported ethical violations are extremely rare in dietetics.

Ethical Dilemmas in Dietetics

As mentioned earlier, the nature of dietetic work heightens the possibility of ethical dilemmas in practice. Food has long been known to be associated with ethical debate given its strong moral- and value-laden meanings. In the preface to the newest edition of "Food, Morals, and Meaning," Coveney (2006) writes "...we can understand that nutrition is not only a science but also an ethos which presents a problem for modern individuals in regard to their food choices and pleasure" (p. xvi). As dietitians are socialized into the profession of food and nutrition, their own beliefs and attitudes combine with those held by the profession. At times, this presents great conflict and tension for the practicing dietitian (Gingras 2005). Several such dilemmas are outlined in the following section.

Ongoing Ethical Dilemmas

Scope of Practice

As the field of dietetics continues to evolve, so too does dietitians' scope of practice. As dietitians venture into new areas of practice, they inevitably encounter new and unique ethical issues. Dietitians currently work primarily in the following areas: clinical practice, foodservice management, research and education, and industry/consulting (Anderson 1993). Specific issues faced by dietitians in these varying practice areas will be outlined in more detail below. However, it is helpful to first think about what types of ethical dilemmas might

be encountered by dietitians working in different domains. Clinical ethical issues include patient autonomy and rights, confidentiality, and artificial nutrition support. Additionally, as dietitians take on new clinical duties such as finger pricking for blood glucose testing or inserting nasogastric tubes to feed those who cannot eat through by the mouth, individual practitioners have an ethical responsibility to only engage in such acts when they feel competent to do so (Steinecke and The College of Dietitians of Ontario 2012). Individuals working in foodservice management face ethical issues related to human resources management, as well as the management of other resources such as money, materials, and time (Anderson 1993). Those working in research and education must deal with plagiarism, knowledge translation and dissemination, and ethical research pertaining to human subjects. Finally, dietitians who consult for or represent industry must be keenly aware of the potential for conflict of interest to arise in their work, which could impact their professional ethics.

Tube Feeding and End of Life

The issue of artificial nutrition support at end of life rose to prominence in the public eye with the case of *Cruzan vs. Director, Missouri Department of Health* (1990), regarding the withdrawal of nutrition support from Nancy Cruzan after she had been in a persistent vegetative state for 5 years after falling victim to a car accident at the age of 26. The issue came to light again with the *Terri Schiavo* case of 2005. In both cases, life support was eventually discontinued for the patient; however, substantial ethical questions remained unresolved (O'Sullivan Maillet 2008). In a position paper put out by the American Dietetic Association on the "ethical and legal issues in nutrition, hydration and feeding," three major ethical frameworks through which end of life care can be viewed, each with a distinct perspective, are outlined. The first is the utilitarian view, most famously purported by Mills in which the ethical option is the one that provides the greatest positive effect and least negative effect on all individuals impacted. The second perspective is Kant's deontological viewpoint whereby certain actions are viewed as inherently right or wrong irrespective

of their consequences. Finally, there is an Aristotelian outlook, which focuses on the virtue of the decision maker (O'Sullivan Maillet 2008). The association maintains that "the patient's right to self-determination [should be] the overriding principle" in decision-making. In cases where an individual is unable to express their own desires, a substitute decision maker should speak on behalf of the patient guided by what they believe the patient would want, even if this is against the said decision maker's personal desires (Andrews and Marian 2006).

In a study on the opinions of Louisiana dietitians on nutrition support and end of life, Langdon et al. (2002) found that a majority of dietitians (60%) were in support of "foregoing, withholding, or withdrawing nutrition support at end of life." Although most dietitians believed that the patient or family are the most qualified to make decisions regarding the matter, 95% thought that the dietitian should be involved to some extent in the decision-making process. However, only half of them felt qualified to provide the necessary information to be of assistance. Interestingly, research has shown that continued nutrition support in terminally ill patients may in fact be detrimental. It can lead to increased gastrointestinal fluids and subsequent vomiting increasing the requirement for nasogastric suctioning, increased respiratory distress and choking due to fluid retention in the pulmonary system, peripheral edema, and increased urine, which may lead to the requirement of catheterization in weaker individuals. Furthermore, terminally ill patients do not usually report hunger and often have little desire for food. The major negative impact of withdrawing nutrition support at this stage of life is dry mouth, which can be alleviated with proper mouth care (Andrews and Marian 2006). For a more comprehensive discussion of artificial nutrition support, individuals should refer to Monturo's (2009) review of the issue as published in the Hasting's Report from 1971 to 2007.

Industry Business and Food Service-Related Ethical Issues

Although dietitians in all areas of practice may at some point be confronted with potential conflicts

of interest, dietitians consulting or working for industry or profit (whether in food service or private practice) must acknowledge this ethical issue on a daily basis. This is because they have obligations to diverse groups of people including clients, customers, managers, partners, and shareholders (Grandgenett and Derelian 2010). One example of an ethical dilemma faced by dietitians in industry is the request to endorse the marketing of a product that may not have substantial scientific evidence to support its use. Alternatively, dietitians may promote a product by citing appropriate scientific evidence, but neglect to disclose their personal affiliation to company or trade association, which is also considered unethical. In the new age of social media, many dietitians maintain personal websites or blogs on which they may endorse certain foods or products. It is not uncommon for companies to approach dietitians with propositions to promote their products in exchange for some sort of material compensation (Grandgenett and Derelian 2010). Even if the compensation takes the form of free samples of the product, this can be considered a conflict of interest. More mundanely, dietitians have also been accused of being co-opted by the diet food industry in their promotion of low-fat foods, which have not been shown to reduce the risk of chronic disease (Austin 1999).

Dietitians working as foodservice managers also face conflicts of interest as food manufacturers may offer incentives or rebates to hospitals that purchase their products over those of a competitor. Even if the organization and not the individual manager receives the incentives, they may still represent a conflict of interest. In these cases, dietitians should follow facility guidelines on the acceptance of gifts, make sure that products purchased meet nutritional guidelines and meet the best interest of patients, and provide full disclosure of both real and perceived conflicts of interest. An ethical dilemma, which is unique to dietitians working in food service, is the issue of employees taking food home. Although at first pass this is tantamount to theft, the action becomes ethically gray in instances where the food is about to expire or is left over and therefore will be thrown out. Furthermore, the act is akin to

managers and other hospital employees taking left over catering home after a meeting. Therefore, this is an issue of institutional culture, and clear policies should be developed based on ethical principles (Barkley 2008).

Body Weight Regulation

Taking “obesity management” as one example, dietitians are currently advised through national practice guidelines to promote “healthy weights” and encourage their patients and clients to lose or gain weight to fit into a body mass index category of “normal.” A wealth of new data exists that this advice is contraindicated and continuing to draw on obsolete weight management advice perpetuates medicalization of the body (Sobal 1999) and weight stigma (Puhl and Heuer 2009; Gard and Wright 2005).

In an era where many individuals living in developed countries have instant access to so much entertainment, information, communication, and even food, there is a desire among many consumers to employ a “quick fix” to meet their weight loss goals. In response to this desire, there are a plethora of dietary supplements that purport the benefit of weight loss, as well as a small number of pharmaceutical products. It is important that dietitians remain up to date with the research and employ evidence-based practice when counseling patients regarding the use of such products (Biesemeier and Cummings 2008).

Research Ethics

The most common ethical breach in scientific research is compromising data integrity. This can take the form of data fabrication or publication of misleading data. Reporting bias, whereby researchers only publish data that are consistent with their research objectives, personal beliefs, or funders’ interests, also falls into this category. Another major issue of academic integrity is the practice of either excluding authors who have significantly contributed to the research or including authors who have failed to do so (Nicklas et al. 2011). An ethical issue specific to healthcare research, especially when carried out in a community setting with underserved populations, is the provision of ancillary care for research participants.

This problem is further complicated in nutrition-based research since food is not merely medically therapeutic, but also a basic aspect of the human experience encompassing social, emotional, and cultural dimensions (Merritt and Taylor (2012). Merritt and Taylor (2012) discuss three potential ethical challenges related to this issue. First, providing such care may impact study outcomes, particularly in trial-type study designs. Second, there is the question of whether any care provided to participants should be offered to the community at large. Third, field workers are typically not clinicians but require adequate training to determine the need for ancillary care, since they are in closest contact with participants and community members and therefore more in tune to their needs.

New Ethical Issues to Consider

Unique Ethical Issues Related to the Aging Population

In recent decades, many countries have gone through a demographic shift resulting in an increasing proportion of older individuals in their populations. Dietitians face many unique ethical challenges when servicing older individuals. Increasing evidence has linked dietary factors to healthy aging as they are not only important for the treatment of chronic diseases, but also for the prevention of such conditions (Leppert 2009). However, food does not only serve a therapeutic purpose in the lives of individuals. What meaning people derive from food is determined by social, emotional, and cultural factors. Therefore, especially for older individuals, food and diet can have an enormous impact on quality of life. The ethical dilemma then becomes, to what extent should a dietitian recommend restricting intake of certain foods in the name of health, when those foods are important to older individuals for other reasons. This issue is further complicated in institutional or community program settings where governments or organizations mandate dietary parameters. For example, dietitians may face questions such as what to do if an 85-year-old with hypertension wants to eat eggs and bacon every morning? Or how should they discuss limiting

sweets with a 94-year-old with diabetes whose blood sugar level occasionally rises beyond clinical guidelines when they eat chocolate bars? Dietitians also need to realize that elderly clients who have limited social contacts and are seen at home are particularly vulnerable to power dynamics in the client/provider relationship (Leppert 2009).

Organizational Ethics and Resource Allocation

As dietitians become more involved in business in both the private and public sector (e.g., taking on more administrative duties within hospitals), they need to begin to think more about the ethics of organizations. Issues arise in the areas of human resources (such as hiring, firing, job and task outlines, and provider fatigue/burnout), internal and external communications, and corporate responsibility (to clients, shareholders, and communities at large). Even non-managerial dietitians need to be thinking about these issues. For example, interprofessional collaboration and dynamics may pose ethical challenges when another healthcare professional provides what a dietitian believes to be misinformation to a patient or client. Dietitians may also think about advocacy for increased positions within a healthcare organization. Although resources are strained, limited dietitian availability in both acute and chronic care settings may be detrimental to both clients who are not getting the best care possible and dietitians who may face burnout.

Food Security, Cultural Competence, and Environmental Sustainability

The World Health Organization defines food security as “when all people at all times have access to sufficient, safe, nutritious food to maintain a healthy and active life” (2013). This definition is often expanded to include notions of acceptability and sustainability. To that end, dietitians need to ask whether the dietary recommendations they make are appropriate given these factors. For example, dietitians may want to consider education of patients or clients regarding sustainable food choices when recommending they consume potentially environmentally harmful foods such as fish. Additionally, some people may not find genetically modified organisms acceptable, while others may feel that

such foods might increase environmental sustainability. It is important that dietitians remain up to date on the evidence regarding such foods so that they are able to make unbiased recommendations while at the same time remaining sensitive to consumer beliefs and values (Roberts et al. 2006). Acceptable foods are also culturally appropriate, and while cultural competence is considered best practice, an argument can be made that it should also be considered ethical practice.

Perhaps the most important component of food security is access. Dietitians need to be aware of diet-related disparities, defined as “differences in dietary intake, dietary behaviors, and dietary patterns in different segments of the population compared to the general population,” and nutrition-care disparities, defined as “differences in access, delivery, and health outcomes of dietetic services offered to people with similar conditions,” which together make up “dietetics-related inequalities” (Fileti 2011). Furthermore, dietitians need to ask themselves to what extent are they personally and professionally responsible to reduce such disparities through actions such as advocacy?

Nutrigenomics

Perhaps the most recent ethical issues to emerge in the field of dietetics are those related to nutrigenomics. Researchers have found links between genetic variance and individuals’ ability to digest, absorb, or be otherwise impacted (either positively or negatively) by certain nutrients as well as their potential susceptibility to nutrition-related chronic diseases. The study of gene-diet interactions and the increasing availability of genetic tests on which clinicians can base recommendations raises questions regarding confidentiality, privacy, and genetic discrimination. Many questions remain unanswered: Should insurance companies have access to the results of such tests? Do dietitians have the duty to warn relatives who may have similar genetic susceptibilities? Should those unable to provide informed consent be tested? Should the testing be made available to minors and those who cannot afford such testing procedures (Reilly and DuBusk 2008)? Additionally, the psychosocial effects of receiving such test results are still unknown (Ryan-Harshman et al. 2008).

Ethical Decision-Making Framework for Dietetics

The framework that follows is but one example of a step-by-step process of ethical inquiry that can be applied to difficult situations a dietitian might encounter in practice. This process can be worked through independently or collaboratively with others representing interdisciplinary practice areas. The benefits of working through such a framework collaboratively are the enhanced veracity of a final decision multiple perspectives can offer. The expectation is to apply the decision-making framework from beginning to end without missing a single step.

1. Problem

Name the problem clearly. Where is the conflict? What are the various perspectives on the problem?

2. Acknowledge Feelings

What are the “gut” reactions? Are there biased perspectives? What loyalties to individuals hold to these varied perspectives? How do such loyalties influence the final decision?

3. Gather the Facts

What are the ethically relevant facts? Whose account of the facts counts most? Have all the relevant perspectives been obtained? What do the institution’s policies or guidelines say? What does the relevant law say?

4. Consider Alternatives

What are the alternative courses of action? What are the likely consequences?

5. Examine Values

What are the preferences of the person receiving care? Are other values relevant? Which of the values conflict?

6. Evaluate Alternatives

What other options are available? What are the implications and consequences of each of those options?

Adapted from http://www.stmichaelshospital.com/pdf/ethics/ethical_decision_making_framework.pdf

By recognizing the ethical dimension to any eating or nutrition issue, dietitians can apply an

ethical decision-making framework to it and then decide how to proceed. Applying an ethical decision-making framework may or may not have a variety of implications. It may or may not change the dietitian's course of action. It also may or may not help the dietitian to feel more at ease with whatever decision they make and whatever course of action they take. However, what the ethical decision-making framework does allow is an opportunity for the dietitian to apply a thoughtful analysis to any particular issue, ideally in a collaborative setting, so as to make a wholly informed decision on how to act.

Areas of Future Inquiry

Given the dearth of evidence demonstrating the effectiveness of applying ethical frameworks in dietetic practice, a first effort in this regard is warranted. Qualitative research with dietitians who consent to be interviewed about their process through ethical dilemmas would also shed light on approaches that buttress "good and right" decisions regarding food and eating. Additionally, there has been no research in dietetics regarding the impact of ethics in the curriculum on decisions made in practice. Curricular interventions, those applied in undergraduate dietetic education, would initiate a more committed professional loyalty to ethical frameworks as well as determine which ethical frameworks are best applied to which ethical dilemmas. Longitudinal studies that follow students into practice and explore the ethical issues encountered and the steps taken to address those issues are ultimately the best determinant of future ethics curriculum.

Summary

Despite ethics being an under-examined topic in dietetics, food and nutrition "experts" encounter many diverse ethical issues in practice. Gender studies, law, ethics, and the humanities can help inform ethical approaches to practice in dietetics. Ongoing research into effective ethical decision-making and education of new practitioners is warranted.

An Introduction to Food Charity

Societal struggles for food security are not new (Allen 1999). Throughout history, ancient civilizations frequently rose to power and collapsed based on their capacity to produce and sustain a secure and stable food supply (Busch and Lacy 1984). As Hopkins and Puchala note, “securing adequate food is one of the oldest problems confronting political institutions” (1978, pp. 3–4). In almost every “industrialized” country, the state has been increasingly shedding its responsibilities for social welfare. In five such countries – the United States, United Kingdom, Canada, Australia, and New Zealand – governments have been changing welfare systems while neglecting the growing issues of hunger and food insecurity (Allen 1999; Riches 1989, 1997). The gaps have been filled instead by emergency food relief programs, such as food banks as well as soup kitchens and food pantries.

Emergency relief is defined as the “provision of financial. . . [and material] assistance to those persons that find themselves in financial crisis” (ACOSS 2011). It has a long tradition, as tribes and more recently the church collected a tithe to support those in the community that were less fortunate (Booth et al. 2014; Caraher et al. 2014). In Europe and Canada, classic welfare systems were established on the “gift relationship” (Titmuss 1970). In France, the system of “solidaritesociale” for social insurance was developed to restore communities after the Second World War (Caraher and Carr-Hill 2007). In Australia, charity food relief dates back to colonial times. The Benevolent Society of New South Wales was created in 1813 to provide “outdoor relief” and rations to protect people from homelessness and hunger, continuing as the dominant

institutional assistance throughout the nineteenth century (Booth et al. 2014; Dickey 1987). Across all of these approaches, a “common good” is assumed. It is widely understood that the alleviation of poverty is good for everyone, with even those who do not directly benefit viewing donation as a social benefit (Caraher et al. 2014).

Over the last decade, the emergency relief sector has changed with the growth of large-scale food rescue organizations. Food rescue, also called food redistribution or food recovery, is the practice of collecting surplus edible food from commercial food businesses and distributing it to welfare agencies that provide food relief. There are now food rescue organizations in around 25 countries and on six continents (Vlaholias et al. 2015; Reynolds et al. 2014, 2015). With ethics that are both humanitarian and increasingly environmental, these organizations aim to reduce the millions of tons of food waste sent to landfill each year and to relieve hunger (NSW Centre for Public Health Nutrition 2003; ABS 1995).

While at first glance food donation appears to address life chances, social inequality, and natural resource wastage, it has been critiqued for perpetuating or even exacerbating social inequality (Poppendieck 1998). As noted by Marcel Mauss, “to give is to show one’s superiority, to be more, to be higher in rank... [but]... to accept without giving in return, or without giving more back, is to become a client and servant, to become small, to fall lower” (1990 [1950], p. 74). Therefore, while donating surplus food provides immediate benefits to recipients, the food industry, and the environment, food charity can have the unintentional effect of disadvantaging the very recipients that it is intended to aid.

In the past few decades since such critiques were first raised, models of food charity have developed rapidly. This is partly due to the increasing recognition of environmental impacts of issues such as food waste, as well as the complex linkages between social inequality and ecological crises. Food rescue organizations are beginning to diversify their work in socially innovative ways that reach well beyond the original food charity provision and include features of “community” food security (e.g., nutritional cooking workshops,

hospitality employment training programs, and community gardens). Still, there is potential for even greater innovation and benefit. In this entry, we discuss previous critiques of food charity as outlined by Poppendieck (1998). We then consider the potential for community food security approaches to address these critiques. We find that community food security approaches are a step in the right direction, but a socially and ecologically innovative model is needed to move beyond “sweet charity” to a more ethical version of community food security that addresses the causes as well as the symptoms of inequality.

Critiques of Food Charity

In her influential book *Sweet Charity?* (1998), Janet Poppendieck suggested that charity food relief programs in the United States were incapable of handling the rising hunger in their communities in an effective, secure, meaningful, or culturally appropriate way. Furthermore, she argued that these programs may have enabled governments to eschew their social responsibilities. Notably, she critiqued:

1. The failure of food charity programs to manage rising hunger, as the amount of food that is rescued is not enough to feed everyone who asks for provision.
2. The deficiency of communication between food providers and the needs and desires of recipients, because the food does not always meet the recipient’s food preferences – be they religious, cultural, or dietary.
3. The nutritional adequacy of the food provided.
4. The unpredictability inherent in a system reliant on charitable donations that ebb and flow based on the needs and priorities of corporate and individual donors.
5. The often random geographical locations of charitable food programs, which develop out of volunteer motivation, rather than assessed need.
6. The disorder of ineffective systems of food collection, reprocessing, and redistribution, the bulk of which is supported by a large amount of volunteer work.

7. The costs to human dignity and social othering (i.e., constructed identities of “haves” and “have-nots”).

Most importantly, Poppendieck notes how food philanthropy has received broad approval from political representatives, the food industry, the media, and the general public, to such an extent that it is often taken for granted as the *only* solution to food insecurity and hunger. As such, charity food relief organizations are becoming increasingly institutionalized and corporatized (Booth et al. 2014; Daponte and Bade (2006); Grell 2010). They are run like big businesses. As a result, the larger and more widespread food charities become, the more food insecurity becomes a depoliticized and private issue (see Lorenz 2012; Poppendieck 1998; Riches 2014; Tarasuk and MacLean 1990; Tarasuk et al. 2014). As Riches suggests, food charities are becoming “a national corporate enterprise of considerable reach and a second tier of the welfare system” (Riches 2011, p. 26). Thus, Poppendieck’s chief concern with food charity is that it is only a “Band-Aid,” short-term approach, and that the more work that charities do, the more governments are able to avoid addressing the most basic human right and need – food (Berner and O’Brien 2004; Lorenz 2012).

Poppendieck encourages people involved in the food charity sector to “look upstream,” analyze the underlying structural causes of hunger, and get involved in advocacy work. However, she explains that there are no clear instructions for doing anything about these underlying causes:

The more penetrating the analysis – the more deeply the causes of hunger appear to be embedded in the globalisation of the economy, the transformation of family and community, and the nation’s mounting appetite for inequality – the more daunting the task becomes, the more likely they are to retreat to a sphere in which they are confident they can make a difference, like a soup kitchen or a pantry. (Poppendieck 1998, p. 290).

Poppendieck highlights that there are many charity food workers who want to go beyond day-to-day feeding, but the more they analyze the pathways that lead people to the food charity door, the bigger the task appears and the more paralyzed they feel to make a change.

Poppendieck and others (e.g., Riches 2011, 2014; Allen 1999) have criticized policymakers for promoting the role of the charity food relief network, praising philanthropy and volunteerism, and expecting food relief charities to fill the gaps caused by government cuts. Exactly how charity food relief organizations in Toronto and Hamilton in Canada responded to Poppendieck’s critiques has been examined by Wakefield (2013). She found that charity food providers’ responses were limited by structural factors restricting their ability to reorganize their aims beyond immediate food provision. Wakefield concludes that organizations often end up both challenging and reinforcing the traditional charity food model.

Community Food Security

A broader approach to food security developed through the community food security movement. Community food security critiques the traditional charity approaches to food security for being disjointed and not focusing on the central goal of developing long-term food security and sustainable food systems (Gottlieb and Fisher 1995). Community food security is a step up from the food charity model, as it reconnects food production and consumption with the aim of ensuring an adequate, accessible, and sustainable food supply. It prioritizes the needs of low-income people and emphasizes local and regional food systems. Many traditional charity food relief agencies have been expanding their work to include aspects of community food security. However, as Allen (1999) has argued, addressing the needs of low-income people and creating a local and regional food system may not necessarily be compatible; in fact it might be conflicting. Advocacy and community food security are important, but they can only go so far in terms of creating significant and long-term changes. There is thus a need to address food security as a symptom of broader structural and systemic issues including inequality, climate change, environmental degradation, population growth, resource depletion, resource conflict, poverty, and unemployment. This project might be advanced through social-ecological innovation (Dennis, Armitage and James 2016).

Social and Ecological Innovation

A socially and ecologically innovative model could help move beyond both the traditional charity model and the community food security model. One solution may lie in developing socially and ecologically innovative models within the structures that are already in place. For example, collaborative and regenerative design processes (see Hirst 2002; Palmer 2017) informed by the permaculture ethics of “earth care, people care and fair share” (Holmgren 2002) could help address such issues. These permaculture ethics could provide a framework for greater understanding of the complex links between social inequality, gender inequality, disability, food and class, and environmental degradation, to help tackle the structural and systemic causes of food insecurity, and build social-ecological resilience.

By engaging all stakeholders through collaborative design, there is potential to avoid over-reliance on market forces, government funding, or volunteerism while being mindful of power differentials within and between different sectors. This could involve participatory action research with stakeholders to collaboratively design and develop socially and ecologically innovative models to reduce food insecurity and build social and ecological resilience. Such participatory research would enable the structural transformation of food charity recipients to producers and donors of ideas, insight and solutions to food insecurity.

In fact, recognizing the important role of recipients as providers of invaluable insider knowledge and relationship brokering could help redress the inherent power inequalities identified by Mauss in the relationship between gift giver and receiver, as outlined above. Another way of addressing the politics of ‘giving’ and ‘receiving’ is to consider sharing as an alternative discourse (Belk 2010). In any case the aim for reconfiguring the politics of food charity, food welfare, and community food security should be to determine a more ethical model for food (re)distribution which goes beyond a symptom-focus to enable the identification of solutions to the causes of food insecurity, including social inequality and environmental degradation.

Ethics of Nutrigenomics

Michiel Korthals

Applied Philosophy, Social Sciences Group,
Wageningen University, Wageningen, The
Netherlands

Introduction

Nutrigenomics is the study of the relationship between genes and food; like all applied sciences, it develops through contact with society. Normative assumptions, embedded in the way

researchers formulate aspects of nutrigenomics research, affect this contact. These assumptions may or may not be in alignment with currently held societal norms and values on food and health. To discuss the possible pros and cons of an alignment of nutrigenomics' assumptions and those currently held in society, one needs to reflect ethically these assumptions. The prominent view on gene-based and customized nutrition embodies at least three normative concepts. First, food is exclusively interpreted in terms of disease prevention. Second, striving for health is interpreted as quantifying risks and preventing diseases through "positive" food–gene interactions. The third normative idea is that disease prevention by minimization of risks is an individual's task. The thesis of this entry is that these concepts on currently dominant customized nutrition will not match easily with the concepts on food and health of various food styles that roam western societies and with a broader view of the relationship between food, health, and the meaning of life. Many people don't want to be a health freak. The non-synchronized coevolution of nutrigenomics and of society due to this mismatch of food styles and values is a challenge for nutrition scientists. To synchronize and optimize the realignment of customized nutrition and society, it is proposed that customized nutrition's research policy changes to a research partnership with society on the basis of fair representation of various food styles, in which health is not the only food value. Some current research programs develop those more encompassing views on customized nutrition.

Nutrigenomics Research: Organization and Assumptions

Organization

Nutrigenomics is directed to contribute to the response of complex health problems, including but not restricted to pandemic risks or the "obesity epidemic." The research covers a variety of specialties and requires a lot of money, collaboration, and interdisciplinary work. Biology, nutritional sciences, and human physiologies are some of

the disciplines to study the gene–diet interaction. The molecular focus on gene sequences and gene expression is the most important. Quite a number of scientists are working in this field of research. In the United States, there are big groups working at UC Davis and with the FDA, in New Zealand we have Nutrigenomics New Zealand (NuNZ), and in Europe we have the DIOGenes and NuGO consortia and the Dutch Nutrigenomics Consortium. In particular, in the first decade of this century, scientists were able to gather a lot of support, and a lot of money went to this undertaking, making nutrigenomics "big science" (Afman and Müller 2012, p. 68). The promise of nutrigenomics to lower public health cost was taken seriously by many policymakers and funding organizations, and many scientists felt that for the first time, nutrition science was being listened to (Penders 2010, p. 13).

Normative Assumptions of a Prominent Script in Nutrigenomics

In Komduur et al. (2009), there are three normative assumptions distinguished in present nutrigenomics research. The authors selected papers written by ten nutrigenomics scientists (Ordovas, Mooser, Müller, Kersten, Afman, Milner, Dwyer, Wahli, Saguy, and Saris), four representatives of the food industry (German, Watzke, Mutch, and Moskowit), and two nutritionists (Trujillo and Davis). Together these most salient normative assumptions on health and consumers comprise a prominent script in nutrigenomics.

As a result of the analysis, it turned out firstly that in the texts chosen, values regarding food are exclusively explained in terms of disease prevention through food. Health is therefore seen as a state preceding a sum of possible diseases, and food has an intervening role in delaying these possible diseases. Secondly, it is assumed that health should be explained as a calculable interaction between food and genes. Health is minimized to quantifiable health risks and disease prevention through food–gene interactions by the "right" food choice. The third assumption is that disease prevention by minimization of risks through the right food choice is the responsibility

of the individual. The individual has to pay attention to make the healthy food choice and to act accordingly on the basis of this personal responsibility either through finding out personal risks revealed through personal tests or through finding out to which risk group he or she belongs.

Together, these assumptions suggest that the good life (a life worth living, with the means to flourish and thrive) is equated with a healthy life, in which risks should be preventively calculated and balanced and in which the individual should have the prime responsibility to act in accordance to the outcome of tests by selecting the right type of food. Persons, who do not accept this task, do not act responsibly. The strong emphasis on health and the positive influence of nutrients in health was for some the reason to call this set of assumptions “nutritionism” (see Scrinis 2008).

A Daily Life Vision on Health

However, views on the relationship between health and food are notorious multi-interpretable and very diverse. This diversity is studied by sociologists; moreover, philosophers have also put forward very different views on this relationship. According to the extensive sociological literature on views in daily life about health and the relationship with one's own body and with food, health is seen as a positive good that concerns the way one feels oneself as a healthy and respected person (Pajari et al. 2006; Payer 1988). This positive state is not determined by feelings of unrest or even concern for the coming of diseases in the near or far future; on the contrary, experiencing the living body and respected interactions is an enduring element of being healthy. Constantly worrying about your health during food choices is seen as an obsession for health and is viewed as a characteristic feature of a health freak and not of a social and convivial friend and relative. When persons are exclusively led by health considerations in their daily life, they are seen as disrupting the solidarity between themselves and their friends and relatives (Bouwman et al. 2009). In particular, food, as a kind of starter, occasion, or even excuse to have interaction and communication with other people, is seen as a social device

par excellence to maintain and deepen preferred social relations and to have conversations. Meals and drinks together are the most common mechanisms to maintain social networks and to share opinions about prospects and problems of life with people one likes. The type of meals and drinks chosen are intrinsically connected with the type of persons one wants to be in interaction with; food is an identity issue. People that do not align easily in the choice for the food chosen for health reasons but look perfectly healthy are seen as health freaks. Stubborn differing from others and always quarreling about the food offered are seen as making fuss about social relationships and not trusting others sufficiently.

In selecting certain types of food, people mostly get their knowledge about food qualities (and therefore also about the healthiness of the food chosen) from relatives and friends that are most trusted, not from scientists (Bouwman et al. 2009). Both with respect to their understanding of food products, as in handling the behavioral and social implications of this information, they rely heavily on their talks with friends and relatives during a meal or a drink (Leathwood et al. 2007). From these already referred to reports on qualitative research on talk about food and health we are confirmed about the range of different topics that according to daily life consumers belong to the issue of health and food, and the association between them that are made, and the way these different aspects are brought in some kind of liveable balance or even harmony (Pajari et al. 2006). In general, it turns out that consumers have quite a broad and multifaceted non-biomedical definition of health, in which personal well-being plays the most important role in connection with social relations.

It is not well known what quantitative surveys say about the frequency and spread of these different views on food and health in the total population, but these reports give ample evidence of the range of different aspects that according to consumers can belong to liveable beliefs of health in relationship with food. They show that there is a coherent view on the good life incorporating a broad concept of health that is quite different from that incorporated in the assumptions of the prominent script of nutrigenomics.

Health in Philosophy: Good Life

Many philosophers have tried to show that it is typical for human beings to ask themselves questions like the following: what do I want in life? What is the meaning of life? What makes my life worthwhile for me and others? Posing those questions implies that living routinely and unreflectively one's life is not really the best thing to do. Due to the fact that human beings have so many diverse potentialities and vulnerabilities, and that life is finite (temporal), it is necessary according to most philosophers to examine what the meaning of life for human being can be. Under the general heading that the complexity of life urges one to examine what one really wants and how to live, the answers of these questions cover different ideas of the good life. The good life is therefore the name for ideals and ideas that are often not reached but are seen as guidelines and that can make individual actions and events meaningful. The answers to the questions of what to live for differ greatly, because some argue in favor of happiness (like hedonism and utilitarianism), others for religion or philosophical meditation (like Plato and Aristotle), others for doing just and good (like Kant), and again others for a life of passion (like Nietzsche). The common thread of the idea of the good life is that human life is only worthwhile in examining its meaning in terms of certain values and putting those values as guidelines and perspectives in living (Komduur et al. 2009; Graham 1990).

Humans should examine what they really want, taking into account their capacities, talents, networks, interactions, and vulnerabilities between birth and death. The idea of the good life therefore covers not only issues of living in a decent, just, or moral way together with other persons but broader also in finding out what the meaning can be of living the way one lives; it is about "human flourishing" in connecting with a broad range of other cherished values, like health, solidarity, and care. It has therefore a personal twist, which is however not to say that it is an individualistic idea (for the following, see also Komduur et al. 2009). Martha Nussbaum, who did a lot in examining the historical and systematic functions of the idea of the good life, argues

that "to the Greeks, 'eudemonia' (happiness) means something like 'living a good life for a human being'. (...) Aristotle tells us that it is equivalent, in ordinary discourse, to 'living well and doing well'" (Nussbaum 1986, p. 6). The idea of the good life is about being respected as a member of the community and about the well-being of the community and future generations as well and therefore of doing and feeling good.

This philosophical emphasis on the broad concept of good life, the broad concept of health (as feeling good), and the relationship of health with other values in life coincides with the definition of the WHO from 1948, where health is seen as "a state of complete physical, mental and social wellbeing and not merely the absence of disease or infirmity."

It is interesting to note that the founding father of human rights, Immanuel Kant, cherished the same opinion on the meaning to food and health. First, in his very influential essay on "What is Enlightenment" (1784, Kant 1949), he connects his ideas about being free, autonomous, and mature in choosing your own food as a kind of third liberation next to being free in saying how the world is (the issue he elaborated upon in his famous first critique of pure reason) and expressing how the world should be (he elaborated upon this issue in his second critique of practical reason):

Laziness and cowardice are the reasons why such a large part of humanity, even long after nature has liberated it from foreign control (naturaliter maiorennes), is still happy to remain infantile during its entire life, making it so easy for others to act as its keeper. It is so easy to be infantile. If I have a book that is wisdom for me, a therapist or preacher who serves as my conscience, a doctor who prescribes my diet, then I do not need to worry about these myself. I do not need to think, as long as I am willing to pay.

Kant never wrote the (third) critique on the gastronomical reason and how to reach maturity in that area, but his most suggestive comments on food are found in his "Anthropology from a Pragmatic Point of View" (1790). In general, he places humans between nature and reason. Man's capacities derive neither from nature nor reason alone but from the two together, where nature stands for

the passions and sensual experience and reason stands for transcending nature by using the faculty of reasoning to know, will, and appreciate (judge). For instance, to enjoy art and food socially means to transcend nature; it is to judge something that is given (nature) but structured according to the standards of judgment that are shared among rational beings (reason; beyond nature). The main thrust of Kant's text is to emphasize what human beings can make of their nature; it is not about how nature has made them. Human beings must embrace the drive toward maturity, must stand on their own two feet, even if they hesitate and stumble in the process. Taste plays a special role here. It has, according to Kant, the extraordinary ability to stimulate reasonable solidarity through enjoyment. Enjoying food once means that you will want to enjoy the meal (together with others) again; this feature marks culture within society. But food is also more than that. A good meal with good people is an occasion on which experience and reason are united in the individual's enjoyment at a given moment, a moment that can be repeated again and again. Good meals engage reason, which acts on the emotions, which in turn stimulate solidarity and humanity. Eating according to reason therefore means to have meals together and to enjoy the reasoning of others; it means also to let health only be one factor in choosing the food.

Since the time of Kant, many developments have taken place; at present many try to connect the idea of the good life and its concomitant idea of human flourishing with ecological and social challenges like environmentalism and consumption (Crocker and Linden 1998). Consequently, a good meal often comprises also ideas about the ethical acceptability of the production processes of food stuffs (Korthals 2004). Nevertheless, just as in antiquity, the idea of good life comprises a broad diversity of values, and health is only one of them.

Lack of Alignment of Nutrigenomics and Daily Life

From the story until now about the three different views on health and food, it can be easily inferred

that there are considerable differences between the prominent nutrigenomics script, the philosopher's view, and daily life views on health and food. The three normative assumptions of the prominent script seem to be contradicted by the other two. Nutrigenomics assumptions simply do not align with ideas, values, and attitudes in daily life. What will be the reaction of the genomics scientists that adhere to these assumptions? A study of the texts quoted in Komduur (2009) gives the most plausible answers of the script to these differences (see also Komduur 2013). One of these answers goes something like this: the consumer needs more reliable and understandable information and more knowledge to make up his or her own mind and to change the usual unhealthy food habits. Here, the solution is to give better information to the consumers (Leathwood et al. 2007).

The second reaction is that because consumers have already access to so much information and they in general know what to do, but are evidently unable to act accordingly, food scientists decide: let's try to seduce the consumer by good-looking products with a health benefit. Promoting certain products is then the second solution to the gap between science and daily life. Therefore, for example, some scientists promote the eating of fish and the use of fish oil (Oken et al. 2008).

However, the issue is, are these scientists not "overdoing" the health scripts too much, in the sense that it is quite impossible for daily life consumers to live according to these exacting types of information, assumptions, advices, or products? For example, the advice to use as often and as much as possible fish oil would mean eating quite distasteful salads or experiencing fish-taste in meat. Would consumers like to do that? Probably not. Moreover, many consumers know about the depletion of fish resources and therefore they will not heed to this advice.

The emphasis on knowledge or information on the relationship between eating certain food stuffs and future health seems for many consumers (and philosophers) only one aspect of the different aspects of life one has to cope with when one wants to have a good life. Other values are at stake

as well, and life's complexity exactly asks everyone to strike a balance between them continuously.

Finally, one has to consider in how far scientists are legitimized to choose for the kinds of soft paternalism in taking care of the healthiness of consumers (Dworkin 2005). Can one ever be so sure about the dominance of the value of health over other values to prescribe the behavioral assumptions of nutrigenomics? Why not change the script and look for different types of nutrigenomics that more align with the complexities of daily life? Will a science push not backfire because so many uncertainties with respect to the relations between genes and food do galore (Korthals and Komduur 2010)? Why should only consumers have to change their life? Should science not produce knowledge and information that is more enabling to deal with the complexities of daily life?

Realigning Nutrigenomics with Daily Life

The differences between normative assumptions and daily life assumptions can probably not be bridged by producing information or new products or, more generally, by a one-sided offense from the side of science (see Korthals 2011). Probably nutrigenomics has also to change its assumptions and research trajectories and to take more into account the complicated web of responsibilities with respect to health. One way to find new bridges is to look to alternative scripts in nutrigenomics, and there are some, for example, the ones that can be called public health nutrigenomics and taste genomics. These other scripts clearly start not from a narrow personalized health perspective but from a broader health perspective or even from a totally different perspective, the genomics of taste. Prof. El-Sohemy from the University of Toronto in his *Nutrigenomics of Taste – Impact on Food Preferences and Food Production*, 2007, for example, outlines issues of the relationship between food, health, and taste. Others, like Khoury and Mensah (2005), develop nutrigenomics in close connection with considerations on common chronic

diseases. By taking into account the embedded meaning of health nutrigenomics, one can formulate more socially acceptable research priorities. The full complexities of health can even better be incorporated by organizing end user panels in the different genomics research trajectories. Many nutrigenomics scientists feel the urge to produce recommendations of food intake, but they forget that their competences and knowledge do not lie in that quite complex field. Therefore, it seems advisable to let recommendations of food based on nutrigenomics be accompanied by social research of its successful applicability.

Summary

In this entry visions of the meaning of health and food in life are discussed in several rounds, and it is argued that a current and prominent script of nutrigenomics is at odds with those of daily life and of philosophy. A better interaction between science, ethics, and daily life could guarantee more fruitful results. It would result in better research priorities, better products, in which better means more socially applicable knowledge and information. The advantages are that by better listening to ethical assumptions of consumers, and by taking the science's and consumers' views seriously, science can have a better impact and can be a more trustworthy partner in tackling the complexities of daily life.

In discussing the relationship between health and food, ethical assumptions are unpacked in personalized nutrition, daily life, and philosophy; they are compared and a manageable realigning of them is proposed. This applied ethics strategy does not use (academic) ethics as a kind of traffic light that gives green or red lights to scientific developments that will either progress or not, but tries to start from explicating ethical assumptions interior to a certain field of practice and then looks for fruitful integration of science and society (Keulartz et al. 2004). The social embedding of science without moral pain means making explicit moral scripts inside science, comparing these scripts of science with that of ethics and daily life ethics and finally looking for alignments.

Introduction

Obesity (BMI ≥ 30) is presented as a major public concern, given its association with multiple chronic diseases. Obese persons are encouraged to lose weight through weight loss dieting and exercising despite long-standing evidence that weight loss dieting does not result in sustained weight loss. Weight loss promotion is premised on the notion that obesity is a product of a simplistic energy imbalance model, i.e., calories in exceeding calories out that can be easily manipulated to produce a 'normal weight' (Gard and Wright 2005). This focus persists despite advancements in obesity science that complicate the simplistic energy imbalance model in terms of population and individual weight trajectories. While the dangers of obesity and the benefits of weight loss are often depicted in the media as incontrovertible, there is considerable debate concerning both of these premises from health and social justice perspectives.

Obesity, having a body mass index (BMI) of >30 kg/m², is associated with numerous health conditions that may negatively affect individuals' health and the healthcare system; however, these associations have not been proven as causal. Discussions of the ethics of obesity often focus on whether obesity constitutes a self-inflicted "lifestyle choice" or a disease and how these viewpoints affect public health policy. These debates often hinge on the acceptability of infringing on individuals' freedoms to eat as they deem fit and if medicalization of obesity will counter obesity stigma. Considerations of justice and fairness are invoked, wherein it is argued that individuals of lower socioeconomic status may be disproportionately affected by obesity risk. This entry focuses on a less explored ethical area by examining the ethical implications of public health's focus on weight loss as a form of obesity treatment and prevention.

What Is Obesity?

Obesity is variously categorized as a benign morphological variant, a lifestyle factor, a risk factor,

and a chronic disease. Labeling obesity a disease has significant social and lifestyle implications. Determining the most accurate label for obesity requires a thorough understanding of obesity's potential causes and health impacts, as well as the sociocultural process of medicalization. While understandings of obesity have often revolved around the concept of excessive food consumption and insufficient exercise, new evidence has emerged on how energy imbalance and environmental and developmental factors may contribute to obesity; the independent effects of fat, diet, and exercise on health; the pathways through which fat and lifestyle may affect health; the stimuli that induce weight regain and the composition of fat that is regained; and the relations between persistent organic pollutants, weight changes, and chronic disease incidence. Considering these advancements is essential for more accurately understanding obesity's effects on the health perceptions, quality of life, and wellness of obese individuals and for developing the most effective health promotion programs and policies for all individuals. However, the focus on the energy balance model and weight loss often supersedes these more complex views on obesity etiology.

Saguy and Riley (2005) divide the primary claimants in this debate as antiobesity researchers, antiobesity activists, fat acceptance researchers, and fat acceptance activists. Antiobesity researchers and activists may or may not contend that obesity is a disease but tend to focus on obesity as necessarily a health issue that can be redressed by individuals' controlling the components of an energy balance equation (calories in vs. calories out). These antiobesity researchers believe that using less extreme or medicalized language when discussing obesity will produce poorer health outcomes given the seriousness of risks imposed by obesity (Saguy and Riley 2005). Obesity, in this view, is a behavioral issue and not an issue of bodily diversity. It is frequently linked to smoking, as a health risk willingly incurred by individuals. While discrimination is now frequently recognized as an obesity health risk or social problem, the behavioral perspective on obesity suggests that obese individuals are willing to risk stigmatization by continuing in unhealthy behaviors.

Medicalization and Obesity as a Disease

The World Health Organization refers to obesity variously as “complex and incompletely understood” and as a “serious” and “chronic” disease. The WHO also acknowledges that increased abdominal fat incurs more risk than more peripherally deposited fat. However, Gard and Wright (2005) contend that their arguments actually suggest that obesity is a cause of disease. Obesity is characterized as a disease because of its associations (based on certain fat distributions) with non-communicable diseases but not because of its effects on health. This is more in keeping with the definition of a risk factor. Some authors have argued that obesity’s reclassification as a disease is a case of medicalization.

Medicalization is the process through which a problem is defined “in medical terms, usually as an illness or disorder, or using a medical intervention to treat it” (Conrad 2005, p. 3). Medicalization is driven by multiple factors including the expansion of the medical profession’s jurisdiction to include previously nonmedically recognized issues, social movements and interest groups that increase the credibility of a particular issue, and pharmaceutical and commercial interests. As medical practice has changed, the process of medicalization has altered. Physicians serve as gatekeepers for the attainment of medical treatment; however, increasingly medicalization is now affected by commercial and market forces. In the 1980s, medicalization of obesity was partially hindered by insurance companies’ unwillingness to pay for gastric bypass surgeries (Conrad 2005). When obesity became increasingly acknowledged as an epidemic, it was subsequently deemed more cost-efficient for the morbidly obese to receive the surgery than to treat potential obesity-related comorbidities (Conrad 2005). Medicare officially recognized obesity as a disease, the criteria for receiving treatment became more lenient, the gastric bypass surgery business proliferated, and through these processes, obesity became increasingly medicalized (Conrad 2005).

Lyons (2009) documents some of the commercial interests that influence the American obesity research landscape. Conferences are arranged to

attempt to encourage insurance companies to pay for weight loss treatment, and pharmaceutical companies fund elaborate campaigns to gain approval for often dangerous weight loss drug treatments. Individuals with medical faculty positions also often run weight loss clinics and serve as paid consultants to weight loss and drug companies (Lyons 2009). These same individuals review academic papers for publication, receive obesity-related research grants, and serve on public health panels that designate public health and research priorities (Lyons 2009). This commingling of commercial interests, research, and public health may result in the downplaying of risks of weight loss treatments and the amplification of the risks of obesity in both media and medical accounts of obesity (Lyons 2009). Given the pervasiveness of these interests, it may also result in a lack of external, critical oversight of obesity research and policy. Indeed, it has been argued that validity claims in weight management research are held to a lowered standard than other forms of research. All of these forces may enhance the medicalization of obesity.

Both antiobesity researchers and fat advocates have conceptualized obesity as a disease. For anti-obesity researchers this serves to emphasize the perceived severity of obesity as a health threat, particularly in the context of an “epidemic,” which emphasizes the widespread public health danger of obesity (Saguy and Riley 2005). Fat advocates similarly frame obesity as a disease to manage stigma. Framing obesity as a disease allows for a mitigation of the stigma that may result from obesity being perceived as a product of lifestyle choices (Saguy and Riley 2005). Obesity, when viewed as a disease, is easier to attribute to the result of genetic or inevitable biological processes, over which an individual may have limited or no control (Saguy and Riley 2005). A disease label may lower discrimination as prejudice against the sick is socially censured; however, it may not benefit obese individuals who do not wish to engage in, or do not have access to, socially validated weight control strategies. As obesity is increasingly being recognized as a chronic condition in biomedical literature (Mauro et al. 2008), this may increasingly

displace blame from individuals, as it highlights the challenges obese individuals face in attempting to lose weight and that obesity often constitutes a lifelong struggle (Saguy and Riley 2005).

Who Argues Against Weight Loss?

A number of interrelated but distinct groups including fat study scholars, critical weight/obesity scholars, and Health at Every Size (HAES) proponents argue against the promotion of weight loss. Some researchers are positioned in opposition to the widely promulgated discourse of the “global obesity epidemic” (Cooper 2010). These stakeholders, operating from a positivist epistemology, critically interrogate the epidemiology and biology underlying messaging about the obesity epidemic. Fat and critical obesity scholars position their work more explicitly within critical social theory. They view messages of the dangers of “the obesity epidemic” and its moralistic, individualistic focus on weight loss as exacerbating other forms of marginalization, including gender, class, and racial disparities. These works may rely on a poststructural epistemology or build on sociological theory in areas of stigma and discrimination. A focus on the high levels of discrimination experienced by larger persons has also been adopted by some clinicians and researchers who did not necessarily argue against weight loss (Cooper 2010). Clinicians arguing for a weight-neutral focus on self-care and health behaviors may align with HAES. Scholars and clinicians operating in these areas are informed by a legacy of fat activists and related popular works that have long argued for fat acceptance as a social justice aim (Cooper 2010).

Weight Loss Efficacy

A large body of evidence supports obesity as a chronic state. In 1992, the American National Institutes of Health (NIH) published the Technology Assessment Statement that concluded that voluntary weight loss and control methods do

not work. The statement also emphasizes the potential risks associated with weight loss such as binge eating, fatigue, and loss of lean mass. Five years later, while certain developments had occurred in understanding the genetic, environmental, and metabolic contributors of obesity, little had changed in enhancing the efficacy of voluntary weight loss methods. More recent studies have confirmed that very few individuals are capable of sustaining weight loss over time. A conservative estimate suggests that over 90 % of weight losers regain weight over time. Indeed, a comprehensive review of weight loss dieting interventions found that over two-thirds of participants regained more weight over time than they had initially lost (Mann et al. 2007). Given these high rates of regain, it is concerning to note that recent findings show that the weight regained does not replace lost bone or lean mass, but instead is mostly composed of fat. Importantly, successful weight losers may be characterized by high levels of disordered eating behaviors. Due to these low rates of efficacy, clinical definitions of “successful” weight loss have altered substantially over time and have settled at advocating for around 5–10 % weight loss (Tomiya et al. 2013).

Successful weight losers must adopt substantial lifestyle changes to maintain weight loss. The National Weight Control Registry (NCWR) includes individuals who have successfully maintained a 30 lb weight loss for over a year. Registrants demonstrate high levels of dietary restraint, frequent weight and food intake monitoring, and regular, ample physical activity. A recent cluster analysis of NCWR registrants, however, documented that while the majority of participants were satisfied with their weight loss and highly active (Ogden et al. 2012), one cluster composed of over a quarter of participants struggled with their weight loss, were dissatisfied with this weight loss, and experienced high levels of stress and depression. An additional cluster composed of approximately 10 % of participants reported frequent skipping of meals and low levels of physical activity. These adverse psychosocial outcomes or maladaptive weight control methods were found in the clusters characterized

by the greatest losses in weight (Ogden et al. 2012).

Recent findings have also helped researchers to better understand the physiological and endocrine changes that occur in obese individuals following weight loss that make sustained weight loss highly unlikely. These changes help stimulate weight regain. MacLean and colleagues (2011) provide a comprehensive review of the state of knowledge on post-obese biological alterations promoting weight regain in humans and animal models. These changes suggest that following weight loss, biological processes exert “comprehensive, redundant, and persistent mechanisms” to restore energy reserve depletions and return to pre-dieting weights (MacLean et al. 2011, p. R581). These processes involve increased hunger, suppressed energy expenditure, enhanced metabolic flexibility, altered neural activity, a decrease in nutrient availability, reduced satiety, an increase in energy efficiency and storage in peripheral tissues, a decline in adipose energy depletion signaling from leptin and insulin, and changes in hepatic, adipose tissue, and skeletal muscle metabolism. Initial weight loss efforts are also complicated by the dynamic nature of the energy balance model, which makes weight loss progressively more difficult and gradual as time proceeds.

Mauro and colleagues (2008) discuss some of the common barriers to effective obesity treatment. One such barrier they identify is a lack of recognition among healthcare providers and patients that obesity is a chronic condition. Limited education is presented on this concept in medical school or residency programs. Patients and providers both tend to assume that weight loss is a cure for obesity and are willing to engage in and prescribe weight loss efforts. However, in order to counter the array of endocrine and neurobiological forces that promote weight regain, individuals may need to engage in surgical or pharmaceutical therapies, in addition to lifestyle changes. Surgery is only an option for severely obese individuals, and weight regain is possible even with these therapeutic supports (Mauro et al. 2008).

Potential Clinical Benefits of Weight Loss

Given how few individuals maintain weight loss, it is difficult to assess the benefits of weight loss in the long term. For example, this means that most datasets assessing whether obesity affects mortality use as a comparator those who have always been thin rather than those who have lost weight. One way of assessing potential benefits of weight loss is to look at intervention studies, which tend to produce minor to moderate weight loss in the short term. The interventions that have proven the most beneficial tend to involve participants with comorbidities or specific risk factors.

Minor intentional weight loss may reduce mortality risk in obese individuals with related comorbidities, but weight loss heightens mortality risk among healthy obese individuals (Bosomworth 2012). Weight loss may improve health-related quality of life but interventions in physical activity and eating may be sufficient to provide these benefits (Bosomworth 2012). Risk of diabetes and stroke incidence may be reduced with weight loss, as might use of medication for diabetes and hypertension (Mann et al. 2007; Tomiyama et al. 2013). Other health indicators improve only minimally and do not correlate to weight loss. This again suggests that confounders may be important to consider in understanding these relationships.

The Diabetes Prevention Program is often cited as the definitive proof that mild to moderate weight loss can help prevent morbidity among those with prediabetes. Those in the lifestyle intervention had a 58 % reduced risk of developing diabetes compared to placebo. This was more effective than the metformin arm of the study. Over long-term follow-up, the lifestyle arm's effectiveness attenuated over time but remained as effective as the metformin arm. Lifestyle participants lost an average of 7 kg by the end of the first year, although they regained most of the lost weight during follow-up. Statistical analyses demonstrate that the lifestyle benefits could mostly be attributed to weight loss; however, participants who made lifestyle changes but did not lose weight also experienced a reduced risk of diabetes. During the post-intervention

period, increased weight loss in any arm was associated with heightened risk of diabetes, potentially due to weight regain. Importantly, other large studies in the area produced more mixed results on the benefits of weight loss, such as the Indian Diabetes Prevention Study, Finnish Diabetes Prevention Study, the Indian Diabetes Prevention Programme, and China Da Qing Prevention Study, but these studies do emphasize the value of modifications in diet and exercise.

The Look AHEAD Study is a very large, NIH-funded trial that is frequently cited as evidence of the possibility of successful weight loss. After a standard exercise and dietary intervention, participants were able to lose weight and sustain mild to moderate weight loss for approximately 4.7 years. Improvements were produced in mobility, sleep apnea, quality of life, CVD risk factors, and reduction in diabetes medication use. However, the study was developed to establish whether weight loss dieting could decrease the incidence of cardiovascular disease (CVD) events in persons with diabetes. The trial failed to demonstrate these benefits, and only low levels of absolute sustained diabetes remission were evident. The trial was therefore halted early for ethical reasons, and there was considerable debate in the press as to whether the trial was “successful.”

Potential Clinical Drawbacks of Weight Loss

While intentional weight loss is often presented as invariably good, harms have been associated with weight loss dieting. Such harms include weight gain, body dissatisfaction, osteoporosis, weight cycling, the release of persistent organic pollutants (POPs), disordered eating, and heightening already highly pervasive discrimination toward obese persons (O'Hara and Gregg 2012; Bacon and Aphramor 2011). Among healthy obese persons, weight loss is associated with an increase in mortality in some studies (Bosomworth 2012). Furthermore, the extreme lifestyle alterations required to sustain weight loss must be

considered, particularly as some weight loss sustainers report high levels of depression, stress, weight dissatisfaction, and meal skipping (Ogden et al. 2012).

In many studies, being of “overweight” status (BMI 25.0–29.9 kg/m²) has been found to be protective of mortality compared to being of “normal” weight. Often, it is only at extreme ends of the weight spectrum that associations with mortality become evident. It is possible to be overweight or obese and metabolically healthy. Furthermore, being physically fit, even when obese, may eliminate the association between obesity and increased mortality (Bacon and Aphramor 2011). All these “obesity paradoxes” would suggest that weight loss is unnecessary or even contraindicated.

Alternative Model: Health at Every Size

Health at Every Size (HAES) proponents argue against a focus on weight loss and present an alternative health promotion model. This model focuses more on promoting healthy behaviors, self-care, and bodily acceptance. According to the Association for Size Diversity and Health (ASDAH), the principles of Health at Every Size are as follows:

1. **Weight Inclusivity:** Accept and respect the inherent diversity of body shapes and sizes and reject the idealizing or pathologizing of specific weights.
2. **Health Enhancement:** Support health policies that improve and equalize access to information and services and personal practices that improve human well-being, including attention to individual physical, economic, social, spiritual, emotional, and other needs.
3. **Respectful Care:** Acknowledge our biases, and work to end weight discrimination, weight stigma, and weight bias. Provide information and services from an understanding that socioeconomic status, race, gender, sexual orientation, age, and other identities impact weight stigma, and support environments that address these inequities.

4. **Eating for Well-Being:** Promote flexible, individualized eating based on hunger, satiety, nutritional needs, and pleasure, rather than any externally regulated eating plan focused on weight control.
5. **Life-Enhancing Movement:** Support physical activities that allow people of all sizes, abilities, and interests to engage in enjoyable movement, to the degree that they choose.

Interventions that adopt a Health At Every Size (HAES) approach are weight neutral but include physical activity, nutrition, and self-esteem-enhancing components. Such interventions have been able to produce positive, sustained diet, behavioral, and cardiometabolic outcomes compared to controls. Negative outcomes, including weight gain, have not been produced (Bacon and Aphramor 2011). HAES proponents often have clinical backgrounds, particularly in the areas of psychology and dietetics. As such, HAES advocates often rely on positivist quantitative research to back their arguments and continue to focus on health outcomes. This differs from the more social justice-oriented framing of other weight loss critics. HAES has therefore been critiqued for a continual focus on modifying individuals' behavior and not redressing structural inequities. An outgrowth of HAES, the Health-in-Every-Respect (HIER) faction, more explicitly focuses on social justice and rectifying health disparities (Aphramor and Gingras 2011).

Ethical Considerations of Promoting Weight Loss

Due to the low efficacy of weight loss dieting, some authors have argued that the promotion of weight loss challenges a number of ethical standards, including those of clinical practice. This is premised on the notion that weight loss dieting is unlikely to produce benefits and more likely to produce harm. Aphramor and Gingras (2011) argue that promoting weight loss violates dietetic clinical ethics. Encouraging clients to lose weight, when its low efficacy, potential harms, and possible health benefits of other lifestyle

changes are well known compromises dietetic ethical standards of beneficence, nonmaleficence, veracity, fidelity, justice, and a caring response. While certainly relevant to dietitians, this could also be extended to other clinicians.

O'Hara and Gregg (2012) argue that a weight-centric public health approach violates the Universal Declaration of Human Rights. They argue that this approach exacerbates pervasive health bias (O'Hara and Gregg 2012). This discrimination affects obese persons' likelihood of marriage, employment, housing, and education. Obese individuals are subject to invasions of privacy in the form of BMI screening. Attacks upon their reputation and honor can be leveled in the form of weight-based teasing and abuse (O'Hara and Gregg 2012). Children have been removed from obese people's homes, and obese people can be trapped in endless cycling (O'Hara and Gregg 2012).

Ten Have and colleagues (2011) discussed the ethical implications of policies developed to prevent obesity, some of which relate to the promotion of weight loss. These include the potential elevation of fear and uncertainty of health risks among those who do not lose weight; stigmatization, blame, and discrimination; inadequate provision of information on other determinants of health; and the dismissal of the cultural value of food. Some proposed weight loss programs involve the dissemination of private information (such as BMI "report cards"), the individual attribution of responsibility for weight loss without an acknowledgment of societal-based causal factors, and infringements on personal liberty and autonomy (Ten Have et al. 2011). In summary, the promotion of weight loss carries with it potential harms that are infrequently considered, as weight loss is presumed to be necessarily beneficial for health.

Conclusion

Obesity is often treated as necessarily pathological and a source of strain on individual health and healthcare systems. Weight loss is presumed to be the solution, and it is purportedly to be possible through lifestyle modifications or surgery. However, some scholars and clinicians argue that the

health claims around obesity are overblown, weight loss is not necessarily possible or beneficial, and that obesity discourse reduces a complex issue to individualistic behavior and moralizes health and body issues. These scholars argue that promoting weight loss violates clinical ethical standards by promoting a very frequently inefficacious and potentially harmful treatment. On a population level, weight loss detractors argue that weight loss promotion potentially elevates blame and discrimination against obese individuals; heightens anxiety; threatens autonomy, liberty, and privacy; and ignores structural drivers of ill health.

Introduction

This entry explores ethical issues concerning ethnicity, ethnic identity, and food in the United States. This entry focuses solely on the United States because of its large diversity and immigrant population. However, there are parallel cases in Canada and England where ethnicity is tied to multicultural societies, recent immigration, and racial classification.

In the US context, food has been used to maintain both ethnicity and symbolic ethnicity for early and more recent immigrants. However, ethnic food can also be a pathway to both understanding new immigrant groups as well as alienating the other, especially racial and ethnic minorities. Ethical debates surrounding how and why we consume ethnic food expand our study of ethnic food especially in the US context.

Ethnicity is largely tied to an understanding of race but has been differentiated as based on culture and ancestral heritage, while race is a constructed category based on perceived physical differences (Gans 1979; Lu and Fine 1995). Ethnic food in the United States historically becomes a significant marker of identity for immigrants, Italian and Jewish, by the 1920s (Diner 2001; Gabaccia 1998). More recently, ethnic food is a marker of community ethnic and religious identity for Latina, African, South Asian, and Middle Eastern immigrants.

The study of ethnicity and ethnic food is interdisciplinary and includes important philosophical and sociological theoretical frameworks. Narayan's work problematizes the ethical aspects of eating ethnic food and particularly the food of the "other." She explores how consumption of ethnic food can be linked to reducing xenophobia. Appadurai examines how the imposed construction of a national cuisine often linked to post-colonial projects and can lead to *gastronomic imperialism*. Heldke introduces and problematizes *cultural food colonialism* as the process of eating food from developing or third-world cultures and how sociohistorical processes like colonialism play a role in how and why we exotify food of the other. These social and philosophical discussions of ethnic food are significant

to understanding the ethical implications of ethnic food and ethnicity.

Exploring Ethnicity, Ethnic Identity, and Food

Key concepts and themes in the discussion of ethnicity, ethnic identity, and food include ethnicity, symbolic ethnicity (Gans 1979), immigrant identity (Diner 2001; Gabaccia 1998), food parochialism, and culinary imperialism (Heldke 2003; Narayan 1997). Community, solidarity, and identity are all important functions of food (Anderson 2005). Abarca (2004) also looks at ethnicity through the lens of authenticity as a creation. This is an ethical issue as it questions who has power in constructing authenticity or who has claim to authenticity?

Ethnicity and Symbolic Ethnicity

Ethnicity is largely seen as a social construction based on shared cultural heritage, and race is understood as a social construction based on shared perceived physical traits. This section explores how ethnicity and symbolic ethnicity can help frame our discussion on ethnic food, ethnicity, and ethics. How ethnicity is displayed is one aspect of the ethnic dimension of food. Ethnicity of white ethnic groups is often more palatable to the dominant group.

Gans historically defined ethnicity in the United States as symbolic ethnicity pertaining to third-generation immigrants and future generations who have been able to successfully assimilate into the dominant culture including Irish, Italian, and Jewish Americans (Gans 1979). Symbolic ethnicity refers to an optional ethnicity available largely to white ethnic immigrants in multicultural societies. In this case, we focus on the United States because ethnic identities are often understood, created, and maintained through food, cultural events, and communities (Lu and Fine 1995).

Isaji (1993) and Van den Berghe (1984) explore approaches to the social scientific

definitions of ethnicity. Isajiw explains that ethnicity is a social construction based on perceived cultural traits that takes place in everyday life (1993, p. 4). Van den Berghe also understands ethnicity as a social concept and (1984) understands food as an expression of ethnicity. “Our cuisine is the symbolic expression of our sociality, first in the intimate domestic sphere, and by extension with the larger group that shares our specific culinary complex: the inventory of food items, the repertoire of recipes, and the rituals of commensalism. Along with language, the food complex becomes a basic badge of ethnicity” (van den Berghe 1984, p. 392). He also claims that food is easier to maintain and share than an ethnic group’s language or religion, so in many ways, food is the key to cultural transmission (Van den Berghe 1984, p. 393). Van den Berghe ultimately argues that the culinary complex is often the easiest way to reinforce ethnic ties and pass on ethnicity (Van den Berghe 1984, p. 393).

Lu and Fine (1995) explore the meaning of ethnic food in their exploration of ethnic restaurants and ethnicity and identity. Their research emphasizes how cultural symbols are used to display ethnicity, and ethnicity “depends on a set of consistent actions that permits others to place an individual in an ethnic category” (Lu and Fine 1995, p. 535). Ethnicity is ultimately realized in the United States through festivals, food, and consumption. Fine and Shun Lu emphasize that like ethnicity, authentic ethnic food is a social construction, and “the secret of the acceptance of ethnic food resides in the harmonization and compromise between seemingly contradictory requirements: being authentic and being Americanized, maintain tradition while unconsciously modifying it” (Lu and Fine 1995, p. 547).

Herbert Gans may have once referred to this type of identity maintenance as symbolic ethnicity, but further research on Italian immigrants reveals that food for Italian immigrants includes varieties of ethnic cuisine, structure (meal times), and rituals that continue to reinforce family and community ties. Food is a way to maintain much more than symbolic ethnicity for many immigrants in the United States.

Memory food is one way that immigrant women recreate a homeland in the American diaspora. Memory food is both a method for remembering one’s ethnic and cultural heritage through cooking with family members and a technique for preserving culinary skills, through the sharing of food preparation. Memory foods are the dishes that are passed on from one generation to another often by grandmothers and mothers rather than through recipes (Camargo Heck 2003, p. 216). Memory food allows immigrants to maintain and renegotiate food traditions and ethnic identities but also create ethnic solidarity (Camargo Heck 2003, p. 217). Ray also explains that foodways are a way for society to understand how immigrants and ethnic groups construct class, ethnic, gender, and religious identities (Ray 2012, p. 43). “The importance of food in immigrant culture makes restaurants, grocery stores, and kitchens important sites where ethnicity is practiced and reproduced on a daily basis” (Ray 2012, p. 198).

Ethnic Identity, Immigrants, and Food

Food has been an avenue for American immigrants to maintain ethnic identities within families and communities. Hasia Diner (2001) and Donna R. Gabaccia’s (1998) historical work on food, ethnicity, class, and immigrant American families demonstrates the significance of food in community and ethnic identity maintenance for Italian, Irish, and Jewish immigrants. Gabaccia’s work highlights how food has been a means of ethnic identity building for Italian immigrants through community and shared meals. Diner adds a class and comparative analysis to Gabaccia’s work as she points out how food was a way of breaking down class divisions historically for Italian, Irish, and Jewish immigrants in the early twentieth century. Vallianatos and Raine (2008) explore how consuming food is linked to constructing immigrant identities for South Asian and Middle East immigrants. Vallianatos and Raine explain that “Food also connects across time and place, and for many migrants, food is an essential component of maintaining connections to home. How and what kinds of food are consumed recall families

and friends left behind, and by continuing to consume both everyday and celebratory food migrants preserve these transnational relationships and enact their companionship with those back home" (2008, p. 357). Food is used to maintain a connection to the homeland, and through the consumption and creation of traditional food, immigrants are able to do this (Vallianatos and Raine 2008, p. 368).

Studying food is a way to also study ethnicity, culture, community, and identity. Gabaccia emphasizes that studying food is a mechanism for studying multiethnic societies (p. 9). American immigrants maintained immigrant foodways because food helped maintain tradition, social distance from other ethnic groups, and social status (p. 51). "American food" was ultimately created as a social construction in opposition to ethnic food in the late nineteenth century by American "cultural elites" (p. 125).

The first wave of acceptance of ethnic food in the United States occurred during the 1960s and 1970s largely because of an increase in immigration and counterculture (Belasco 1989; Johnston and Baumann 2010). However, "ethnic food" must be placed in a contemporary sociocultural context. Hippies and counterculture groups often saw ethnic food as an alternative to imperialism and capitalism (Gabaccia 1998, p. 212). "For some counter-cultural Americans, seeking a healthier way to eat returned them to their own ethnic traditions. Vegetarian and healthful versions of ethnic foods developed alongside the traditional ethnic fare offered at food festivals and featured in community cookbooks in the 1970s" (Gabaccia 1998, p. 214). "By the 1980s 10 % of all restaurants in the US were ethnic. The majority of these ethnic restaurants were Chinese, Italian and Mexican" (Gabaccia 1998, p. 218). By the 1990s, foodie tastes favored the natural, organic, and exotic which also welcomed ethnic cuisine (Johnston and Baumann 2010). This was also partly because of globalization and the continuing increase of immigration in the United States. But ethnic food also became one understanding of multiculturalism and symbolic ethnicity. Eating ethnic food was one way that Americans often viewed themselves as

multicultural, open, and tolerant. Food can be viewed as a gateway to inclusive cultural practices, perhaps decreasing xenophobia. Abarca's work examines the ethical dimensions of ethnic food consumption.

Abarca's (2004) research explores and questions how society defines and understands ethnic food. She explores and questions the cultural acceptance of ethnic food into dominant American culture, as well as how ethnic food is perceived in terms of real or imagined authenticity. Who has ownership or access to ethnic and or authentic food is an important ethical and philosophical aspect of studying food and ethnicity. She explains that "Without undermining the positive consequences of ethnic food consumption, an overly enthusiastic focus on these social effects can result in creating a deceiving notion of accepting ethnic minorities into mainstream culture" (Abarca 2004, p. 6). Food is often the one aspect of new immigrant communities that dominant cultures find digestible, but she expresses caution pertaining to this perceived acceptance. Secondly, she calls into question how authentic food is understood. Like ethnicity, authenticity is also a social construction. "Claims of authenticity in ethnic cookbooks and restaurants demonstrate the ideological complexities embedded within the phrase, 'authentic ethnic food'" (Abarca 2004, p. 10).

Johnston and Baumann (2010) explore how ethnic connection is an important aspect of how "foodies" understand authenticity in relation to food. The authors define foodies as those who self-identify as having a strong interest in the "education, identity, exploration, and evaluation" of what they perceive as good food (2010, p. 61). Foodies tend to believe that particular ethnic cuisine should be cooked by specific ethnic groups; sushi should be cooked by Japanese and samosas should be made by Indians. How foodies understand authentic food raises ethical issues about how authentic and ethnic food is defined and who defines these terms. This desire for authentic food often results in reductionist understandings of racial and immigrant groups. Johnston and Bauman emphasize that the ethics in assuming ethnic immigrants or racial minorities can inherently cook the food of their cultural ancestors is

problematic and often leads to reinforcing cultural stereotypes.

Culinary Imperialism, Gastronomic Imperialism, Food Parochialism, and the Future of Ethnic Food

Ethnic food also has ethical and political concerns. Recent research has shed light on issues of power and privilege as they relate to ethnic and exotic foods. Appadurai introduces the term *gastronomic imperialism* as a type of cultural imperialism in which dominant forces impose culinary concepts and values onto a subordinate society or culture. Appadurai's work on Indian cuisine and cookbooks reveals one type of *gastronomic imperialism* with the British-imposed creation of curry as the national cuisine of India. Indian food became the ethnic other as a result of British colonialism. But curry became a fabricated national cuisine as a result of British rule. Appadurai explains, "What we see in these many ethnic and regional cookbooks is the growth of an anthology of naturally segregated images of the ethnic other, a kind of ethnoethnicity, rooted in the details of regional recipes, but creating a set of generalized gastroethnic images of Bengalis, Tamils etc." (Appadurai 1988, p. 15). These generalizations of the gastronomic other erase the specific details of regional ethnic cuisines.

In *Exotic Appetites*, Heldke (2003) introduces the concept of *cultural food colonialism*. She explains that this refers to cooking and eating ethnic foods from "economically dominated" or third-world cultures (2003, xv). Cultural imperialism refers to imposing dominant cultural and social practices, while cultural food colonialism refers to appropriating these practices (xviii). Food adventurers are often engaged in food colonialism as they see eating as an expedition (xxiii). Heldke emphasizes that food adventurers come from privileged class and often racial positions, and therefore, the ethics of privilege come to the forefront of her analysis. Ethnic food rather than ethnic peoples is often more welcomed by food adventurers in privileged positions (Johnston and Baumann 2010, p. 102; Abarca 2004).

Uma Narayan (1997, p. 180) welcomes the eating of other cultures over "food parochialism." She explains that she grew up in a family and community where strict dietary restrictions associated with caste, class, and religion often reinforced strong boundaries and that eating the food of "others" allows for more openness to other cultures, perhaps allowing for less xenophobia. "Growing up in a context where food was intimately connected to caste status and various regimes of purity, it is food parochialism that tends to strike me as dangerous, while a willingness to eat the food of 'Others' seems to indicate at least a growing democracy of the palate. While eating ethnic foods in restaurants might result only in shallow, commodified, and consumerist interaction with an 'Other' culinary culture, it seems preferable at least to the complete lack of acquaintance that permits the different foods of 'Others' to appear simply as marks of their strangeness and 'Otherness'" (Narayan 1997, p. 180).

Kershen's research highlights that xenophobic attitudes in society were often reflected in food racism, culinary imperialism, and food colonialism, because food can also be a source of racial stereotyping (Kershen 2002, pp. 2–8). Jan Whitaker's (2005) work on the Anglo-American home highlights themes of race and food purity in the American context.

Summary

Ethnicity and ethnic food by nature are social constructions and, therefore, will continue to evolve as the makeup of societies and immigrant populations change. In the US context, food has been used to maintain both ethnicity and symbolic ethnicity for early and more recent immigrants and more recently is an avenue for creating community and passing on one facet of ethnicity to the next generation. Ethnic food can also be a pathway to both understanding new immigrant groups and alienating the other, especially in the case of racial minorities. Heldke, Appadurai, Abarca, and Narayan's theoretical perspectives are important in understanding the ethics of culinary colonialism and ethnic food.

EU Regulatory Conflicts Over GM Food

Les Levidow

The Open University, Milton Keynes, UK

Synonyms

[Agricultural biotechnology](#); [GM foods](#)

Introduction

Since the 1980s agricultural biotechnology has been promoted as a symbol of European progress and political-economic integration. Policy language has focused on “modern biotechnology,” encompassing various techniques, yet policy measures have favored genetic modification techniques and their products. According to proponents, agbiotech provides a clean technology for enhancing eco-efficient agro-production. By the late 1990s, however, this technological trajectory was stigmatized as suspect. It was being called “GM food,” or *OGM* in Romance languages or *Gen-Müll* (garbage) in German. The trajectory became negatively associated with factory farming, its hazards, and unsustainable agriculture. GM products have generally faced commercial and/or regulatory blockages to market access in Europe.

In the 1990s controversy over agbiotech in the European Union (EU), proponents criticized opponents for unfairly targeting or blaming a

benign technology as a symbol of wider issues, such as industrial agriculture and globalization. As this complaint illustrates, proponents often draw distinctions between a technology and its context or consequences, while critics generally emphasize links between them. Indeed, technological controversy involves power struggles over how to define the issues at stake, even the nature of the technology. How can the conflict be explained? What can be learned from this experience for other new technologies?

Making Europe Safe for Agbiotech

Since the 1980s the European Union (EU)'s integration project has promoted biotech as a symbol of progress. By the early 1990s, biotech further epitomized promises of a "knowledge-based society," promoting capital-intensive innovation as essential for economic competitiveness and thus European prosperity (CEC 1993). New policies were being designed for a "competition state," directing resources toward the domestic capacity for global competitive advantage (Cerny 1999).

This featured efforts to attract private-sector investment, to subordinate public-sector research to private-sector priorities, to marketize public goods, and to generate globally competitive knowledge. According to this narrative, eco-efficient technologies would bring a competitive advantage and thus societal benefits, but Europe risks losing these benefits through inadequate financial rewards or overregulation. New policies sought to make Europe safe for agbiotech as normal products.

EU agbiotech policy was also linked with a trade liberalization agenda by invoking objective imperatives of global competition. In parallel, the European Commission promoted agbiotech as essential for economic competitiveness and thus for survival of the European agri-food sector as well as its techno-scientific capacities. By the mid-1990s EU-US discussions were identifying "barriers to transatlantic trade," which must be removed through regulatory harmonization, especially for biotech products as a test case (Murphy and Levidow 2006).

Through EU decision-making procedures, regulatory criteria internalized biotechnological models of the socio-natural order. Under the EC Deliberate Release Directive, member states must ensure that GMOs do not cause "adverse effects" (EEC 1990); the scope of "adverse effects" was left ambiguous, to be clarified for each product in its context. Some member states warned that GM crops could generate herbicide-tolerant weeds or pesticide-tolerant pests, but official EU risk assessments classified such effects as merely agronomic problems. This normative judgment accepted the normal hazards of intensive monoculture while also conceptually homogenizing the agricultural environment as a production site for standard commodity crops. Through a technicist harmonization agenda, Europe was being de-territorialized as a purely economic zone, devoid of cultural identities (cf. Barry 2001, p. 70).

Thus early EU regulatory procedures incorporated policy assumptions of the agbiotech promoters. Under "risk-based regulation," societal decisions on agbiotech were reduced to a case-by-case approval of GM products, within a narrow definition of risks, placing the burden of evidence mainly upon the objectors. Each time the Commission proposed to authorize a GM product, it gained a qualified (2/3) majority in the comitology procedure representing EU member states, where dissent was marginalized.

These decisions complemented the wider policy framework of higher productivity for economic competitiveness, as an expected benefit from agbiotech products. This agenda was depoliticized by invoking objective imperatives such as globalization, treaty obligations, and "risk-based regulation." By the mid-1990s, EC policies were making Europe "safe" for agbiotech to achieve commercial success while subordinating regulatory criteria to economic competitiveness.

The technology was being coproduced along with a marketization of nature and society (Jasanoff 2004), in the name of eco-efficiency improvements for agriculture. Regulatory procedures authorized "safe" GM products, which could then enter the EU internal market as extra options for farmers. They would have the free choice to buy more efficient inputs for global

competitiveness. As unwitting consumers of GM food, the public would effectively support a beneficial technology serving the common good of Europe. Within this model of rational market behavior, members of various European publics had little scope to act as citizens.

Putting Agbiotech on Trial

By promoting agbiotech within a neoliberal framework, the EU system provoked great suspicion and even opposition, which grew from the mid-1990s onward. Agbiotech was turned into a symbol of anxiety about multiple threats: the food chain, agro-industrial methods, their hazards, state irresponsibility, and political unaccountability through globalization. The controversy often gained large public audiences through the mass media, as well as active involvement of many civil society groups. They took up concepts from small activist groups as well as from high-profile campaigns of large NGOs. Together these activities developed citizens' capacities to challenge official claims and created civil society networks to which governments could be held accountable.

These activities criticized, used, and eventually reshaped the EU regulations. Demands for accountability took the form of various formal and informal trials. These dynamics continuously expanded trials, defendants, and arenas – what was put on trial, how, where, and by whom. Such trials arose along three overlapping themes – safety versus precaution, eco-efficiency versus agro-industrial hazards, and globalization versus democratic sovereignty – as shown in this section.

Safety Claims Versus Precaution

Lab and field trials were intended to generate evidence of product safety, thus demonstrating a scientific basis for expert risk assessments, which in turn could justify commercial authorization of GM products. Yet safety science became contentious. Expert safety claims underwent criticism for bias, ignorance, and optimistic assumptions (Levidow et al. 2005). Such criticism gained force from suspicion that public-sector scientists had lost any independence from agbiotech promotion.

When France led the EU-wide approval of Bt insecticidal maize 176, its favorable risk assessment was widely criticized by member states as well as NGOs. When France further proposed to approve maize varieties derived from Bt 176 in 1998, Ecoropa and Greenpeace filed a challenge at the *Conseil d'Etat* (the French administrative high court) on several grounds: that the risks had not been properly assessed, that the correct administrative procedures had not been followed, and that the Precautionary Principle had not been properly applied. These NGO arguments gained some support in the court's interim ruling. Thus a government was judicially put on trial for failing to put a GM product on trial in a rigorous way.

When UK lab experiments claimed to find harm to rats from GM potatoes, the disclosure led to trials of other kinds. The project leader, Arpad Pusztai, questioned the safety of GM foods on a television program. He was soon dismissed from his post and was then subjected to character assassination by other scientists. His experimental methods were criticized by a Royal Society report. International networks of scientists took opposite sides on that issue. Environmental NGOs put his employers and other persecutors symbolically on trial, by attributing their actions to political and commercial motives (Levidow and Carr 2010, pp. 100–102).

When a Swiss lab experiment found that an insecticidal Bt maize harmed a beneficial insect (lacewing), expert authority was put on trial. Criticizing the experiment, other scientists cast doubt on its methodological rigor and its relevance to commercial farming, as grounds to discount the results in the regulatory arena. In response, agbiotech critics reversed the accusation: they raised similar doubts about the rigor of routine experiments that had supposedly demonstrated safety. Potential harm to nontarget insects remained a high-profile issue, attracting further research and expert disagreements. Citing scientific uncertainties, some regulatory authorities rejected Bt maize or demanded that its cultivation be subject to special monitoring requirements at the commercial stage, thus further testing safety claims and elaborating test protocols (Levidow and Carr 2010, pp. 182–83).

In the latter two risk issues, surprising experimental results were deployed to challenge safety claims, optimistic assumptions, and expert safety advice. When new evidence of risk was criticized for inadequate rigor or relevance to realistic commercial contexts, similar criticisms were raised against safety claims and their methodological basis. Regulatory authorities were put symbolically on trial for failure to develop adequate scientific knowledge for risk assessment, instead depending on companies for test data.

For the safety assessment of GM food, EU regulatory procedures and criteria likewise were put on trial. Under the EU's Novel Food Regulation, for example, GM products could be approved via a simplified procedure in cases where they had substantial equivalence with a non-GM counterpart. After such approval decisions about several foods derived from GM maize, Italy banned them partly on grounds that the decisions had inadequate scientific evidence to demonstrate substantial equivalence. The Commission sought to lift the ban and so requested support from the EU regulatory committee of member states in 2000, thus putting Italy on trial by its peers. But they instead sided with Italy while also criticizing the regulatory shortcut under the Novel Food Regulation.

After this role reversal, the Commission abandoned substantial equivalence as a statutory basis for easier approval of novel foods (EC 2003a). In risk-assessment procedures, substantial equivalence continued as a "comparative assessment"; this was broadened to encompass more methodological issues, scientific uncertainties, and types of scientific evidence (Levidow et al. 2007). Such comparison with conventional products has remained contentious among member states as well as civil society groups.

Globalization Versus Democratic Sovereignty

Given that agbiotech promoters emphasized globalization as an imperative for GM products, critics could portray them as a threat and agent of "globalization." Since the mid-1990s field trials have been meant to demonstrate the agronomic efficacy and safety of GM crops, as well as the diligent responsibility of the authorities in avoiding any

environmental harm. However, the fields were turned into theatrical stages for protest. They used an "X" or biohazard symbol to cast agbiotech as pollutants and unknown dangers, thus justifying sabotage as environmental protection. When facing prosecution, activists used the opportunity to put the state symbolically on trial for inadequately evaluating or controlling GM crops, as a failure of responsibility.

Activists appealed to democratic sovereignty when carrying out and defending sabotage actions on field trials. The UK government implied that decisions about GM crops lay elsewhere, beyond its political control; this claim was denounced as an irresponsible, undemocratic surrender to globalization. As a response to deferential regulatory decisions, such as the UK government's above, opponents defended sabotage as democratic accountability. Further to the French example above, in 1998 the WTO approved higher US tariffs against several specialty foods including Roquefort cheese, as compensation for lost exports of US beef. *Paysan* activists attacked McDonalds as a symbol of WTO rules forcing the world to accept hazardous *malbouffe* such as hormone-treated beef and GM food. As defendants in court, *paysans* sought to put "globalization" on trial, represented by the French government as well as biotech companies.

Democratic sovereignty also became an explicit theme in judicial trials and regulatory procedures. When some EU member states explicitly refused to support authorization of any more GM products in 1999 onward, they were demanding precautionary reforms in EU rules and regulatory criteria. At the same time, this defiance was turned into a public symbol of European sovereignty versus globalization driven by the USA.

Democratic sovereignty became general grounds to justify measures or actions restricting GM products at the national or regional level. By the late 1990s fewer member states were willing to support Commission proposals to approve new GM products. Some signed formal statements that they would refuse to do so. Lacking a qualified majority, in 1999 the EU Council effectively suspended the decision-making procedure for new GM products; this move was widely called the *de facto* moratorium. Meanwhile some

member states also banned GM products that had gained EU-wide approval (Levidow et al. 2000).

“Globalization” also framed conflicts over GM labeling. The originator of GM soya, Monsanto, was denounced by various NGOs as a global bully “force-feeding us GM food.” Before the European Commission approved GM soya in 1996, NGOs and some member states demanded mandatory labeling for all GM foods. However, this demand was rejected, with warnings that any such requirement would provoke a WTO case against the EU.

On this basis, the no-labeling policy became vulnerable to attack as globalization undermining consumer choice and democratic sovereignty. Local protests at supermarkets demanded GM labeling and non-GM alternatives, in campaigns linked with Europe-wide consumer and environmentalist groups. By 1998 European retail chains adopted voluntary labeling of their own-brand products with GM ingredients. Companies variously labeled their products as “contains GM” or as “GM-free,” in compliance with different criteria established by EU member states. Meanwhile NGOs carried out surveillance of GM material in food products, some not labeled “GM,” in order to protest against them and to warn consumers.

Together these regulatory inconsistencies and protests potentially destabilized the EU’s internal market for processed food products. So the EU established more comprehensive standard criteria; these went beyond detectability and so required an audit trail of paper documentation. Eventually EU law required comprehensive GM labeling and traceability of GM material (EC 2003b), encompassing a broader range of products than before.

GM products also faced a commercial boycott. By the late 1990s, all European supermarket chains excluded GM ingredients from their own-brand products, rather than label them as “GM”; some mentioned precaution and/or consumer choice as reasons. By now GM ingredients were relegated to animal feed from two main sources: imported GM soya was still used in some animal feed, though some suppliers advertised “GM-free” meat or poultry. Bt insecticidal maize was (and still is) widely cultivated in Spain, where

nearly all maize enters a common supply chain for animal feed.

Eco-efficiency Versus Agro-industrial Hazards

Agbiotech began with a cornucopian promise. With precisely controlled genetic changes, GM crops would provide smart seeds, as eco-efficient tools for sustainably intensifying industrial agriculture. These promises were extended by the “Life Sciences” project, featuring mergers between agro-supply and pharmaceutical companies, in search of synergies between their R&D efforts. Its narrative promised health and environmental benefits as solutions to general societal problems.

Critics turned agbiotech into a symbol of multiple threats (Levidow 1996). Productive efficiency was pejoratively linked with agro-industrial hazards; for example, the epithet “mad soja” drew analogies to the BSE epidemic. Biotech companies were accused of turning consumers into human guinea pigs.

Through politically constituted cultural meanings, agbiotech was put symbolically on trial as an unsustainable, dangerous, misguided path. In France, critics cast agbiotech as *malbouffe* (junk food), as threats to high-quality *produits du terroir*. In Italy GM crops were cast as agro-industrial competition and “uncontrolled genetic contamination,” threatening diverse, local-quality agriculture. Using the term *Agrarfabriken* (factory farm), German critics linked agbiotech with intensive industrial methods, threatening human health, the environment, and agroecological alternatives. Institutions faced greater pressure to test claims that GM crops would provide agro-environmental improvements as well as safety.

Those informal trials shaped conflicts over regulatory criteria from the mid-1990s onward. When EU procedures initially evaluated GM crops for cultivation purposes, they were deemed safe by accepting the normal hazards of intensive monoculture. This normative stance was portrayed as a scientific judgment while casting any criticism as irrelevant or political. Yet such hazards were being highlighted by critics, framing risks in successively broader ways. Their discourses emphasized three ominous metaphors:

“superweeds” leading to a genetic treadmill, thus aggravating the familiar pesticide treadmill; broad-spectrum herbicides inflicting “sterility” upon farmland biodiversity; and pollen flow “contaminating” non-GM crops.

These ominous metaphors expanded the charge sheet of hazards for which GM products were kept on trial. Moreover, these broader hazards would depend on the behavior of agro-industrial operators, which consequently became a focus of prediction, discipline, and testing. Regulatory procedures came under pressure to translate the extra hazards into risk assessments. In its risk assessment for GM herbicide-tolerant oilseed rape, Bayer claimed that farmers would eliminate any resulting herbicide-tolerant weeds and so avoid weed-control problems, but Belgian experts questioned the feasibility of such measures. Citing that advice, the Belgian national authority rejected the proposal to authorize cultivation uses, rather than invite the company to test extra hazards. So a proposal went forward only for food and feed uses, gaining EU approval on that limited basis (EC 2007).

GM herbicide-tolerant crops had been promoted as a means to reduce herbicide usage and thus to protect the environment. But UK critics portrayed more efficient weed control as a hazard: broad-spectrum herbicides could readily extend the “sterility” of greenhouses to the wider countryside, which would be turned into “green concrete.” The UK government was widely criticized for ignoring the agro-environmental implications. The Environment Ministry eventually took responsibility and funded large-scale field experiments, to simulate and thus predict farmer behavior in spraying herbicides. These trials were meant to facilitate the “managed development” of such crops. But experimental results indicated potentially greater harm from some GM crops than their conventional counterpart. These results led to a regulatory impasse for GM crops that could have been approved by the UK. Through a more precautionary regulatory procedure, agro-industrial efficiency was cast as an environmental threat to be investigated and avoided.

From the UK controversy in particular, the EU system underwent pressure to broaden the

potential effects and their causes that warrant evaluation. The de facto EU moratorium led to a revised EC Directive, which broadened risk-assessment criteria to encompass any changes in agricultural management practices, such as in herbicide spraying, as well as indirect and long-term effects (EC 2001). This broader scope potentially accommodated dissent into regulatory procedures, but public and expert debate continuously questioned safety assumptions. Broader accounts of harm meant greater uncertainty about whether GM crops could generate such harm in the agro-food chain, so risk assessments needed to anticipate human practices as well as their environmental effects.

Coproduction of Biotechnologized Nature

Agbiotech had been originally promoted as a “clean technology” enhancing natural properties: through precise genetic changes, GM crops would efficiently use natural resources to combat plant pests and to minimize agrochemical usage, thus developing sustainable agriculture. Such beneficial claims were challenged along several lines: safety versus precaution, eco-efficiency versus agro-industrial hazards, and globalization versus democratic sovereignty. The entire development model – now called “GM food,” or *OGM* in Romance languages or *Gen-Müll* (garbage) in German – was negatively associated with factory farming, its health hazards, and unsustainable agriculture. The would-be new order was stigmatized as an abnormal, dangerous disorder.

Agbiotech was turned into a symbol, object, and catalyst for multiple overlapping trials. The defendant symbolically on trial was expanded from product safety to biotech companies, their innovation trajectory, regulatory decision-making, expert advisors, and government policy. Europe was told that it had no choice but to accept agbiotech, yet this imperative was turned into a test of democratic accountability for societal choices. In these ways, protest challenged the democratic legitimacy of a biotech-driven development pathway, as well as a European

integration model for further commoditizing natural resources and redesigning agriculture accordingly.

Opposition activities criticized, used, and eventually reshaped EU regulations. These were originally meant to marginalize citizens' involvement or to accommodate public concerns, in ways facilitating an internal market for agbiotech products, but instead the regulatory framework itself became more contentious. By the late 1990s agbiotech was being coproduced with representations of biotechnologized nature as suspect, potentially abnormal and warranting continuous surveillance.

Summary

The Introduction posed these questions: How can the conflict be explained? What can be learned from this experience for other new technologies?

Commentators have drawn various lessons, including some dubious ones. For example, "The easiest way for the nanotechnology community to avoid the problems experienced in the deployment of biotechnology is to provide accurate information and encourage critical, informed analyses" (McHugen 2008, p. 51). This attributes the earlier public controversy to a deficit of publicly available information, yet its reliability and accuracy were contested, in a context where greater knowledge generally led to greater opposition.

Another lesson often heard was that the next novel technology could become "another GM" if the public is not adequately consulted at an early stage. Conversely, it is also said that greater public involvement or deliberation could help to avoid societal conflict over technological innovations. For example, "Given the opportunity to deliberate on such innovations, the public voice can be expected to be measured and moderate" (Gaskell 2008, p. 257).

Each in their own way, those two distinct lessons decontextualize technology from its political-economic agendas. From the 1990s agbiotech conflict, there are less comfortable lessons, namely, that:

- Technology always presupposes a specific form of the socio-natural order, thus preempting other choices of societal future.
- Societal conflict arises from such non-choices.
- Technology, information, and even deliberation cannot remain credibly neutral in relation to those choices.

In sum, Europe was told that it must accept agbiotech, whose design and policy context potentially naturalized a specific future society, as if objectively required. Yet this supposed imperative was turned into a test of democratic accountability for societal choices. Therefore, prospects for avoiding "another GM" controversy – or perhaps for creating one – depend upon how a technological innovation models the socio-natural order and how state bodies attempt to promote that order.

European Cuisine: Ethical Considerations

Introduction

First used in English in 1786, the word “cuisine” is a borrowing from French, but ultimately from the Latin verb *coquere*, to cook. In French (and in the other Romance languages), “cuisine” can mean simply “kitchen” as well as the collection of foods and food preparation techniques. A general definition of the word as used in English could be “the shared set of food and food-related traditions having to do with its preparation particular to a given era, region, or ethnic/national group.”

Though all humans are biologically omnivorous and can theoretically eat an astounding variety of foods prepared with a wide range of cooking techniques, in practice, social groups – be they defined by nation, religion, class, or other factors – agree that certain theoretically edible foods are not acceptable as food in certain moments or by certain people. While the term “cuisine” is often used to refer to a more refined way of cooking available only to those with a higher socioeconomic status (as distinct from the more mundane, everyday cooking of the majority of a group’s members), the choices that define a culture’s cuisine were and continue to be linked to ethical considerations.

These interlocking concepts can be represented graphically like this: inside of the set of all potentially edible foods, one can put a subset of a particular group’s conception of “food”: for Moslems, for example, cheese would be inside “food” and pork outside it, whereas for most Chinese, the two would be reversed. Within “food,” however,

Eucharist

► Eating and the Christian Church

can represent certain culinary traditions as a smaller subset or privileged foodways, cuisine. Ultimately, an even simpler definition would be “the sum of a number of choices that individuals in a group make about what is good to eat, and what is not.”

The Neolithic and the Birth of Cuisine

Though there was certainly differentiation between groups, archeological and paleopathological research suggest that humans’ hunter-gatherer ancestors likely did not have within-group differences in diet. Except in areas of exceptionally rich flora and fauna (e.g., estuaries), hunter-gatherers had to move frequently in order to follow game and avoid exhausting wild foods on which they relied. This nomadism meant enforced material simplicity: without ceramics and other tools, elaborate meal preparation was impossible. Thus we cannot speak of a “cuisine” before what has been perhaps euphemistically called the “Neolithic Revolution,” the advent of agriculture. The same paleopathological studies that show the excellent health and varied diet of pre-Neolithic humans reveal a dramatic decline in the health of the common person thereafter (Diamond 1999). While arguments have been advanced for the fundamental role of cooked food in the development of modern humans (Wrangham 2010), it is difficult to reconstruct to what extent ethical-religious choices affected the Paleolithic human’s diet.

Food historian Massimo Montanari argues that it is not simply fire and its application to food that creates cuisine, but rather civilization which invents the boundaries that define it. Montanari, while allowing that fire and cuisine do not always coincide perfectly (e.g., oysters on the raw), nevertheless summarizes the relation between these elements: “fire > cooking > kitchen > cuisine > civilization” (2006). Human society had become, in these early civilizations, remarkably stratified by, among other things, alimentary norms. A farmer’s diet was based primarily on cereals, while the higher up the socioeconomic ladder one went, the more varied the fare was, and the more elaborate was the preparation. Jean Bottéro, discussing the

cuisine of ancient Mesopotamia, notes that the recipes that have survived would have demanded not only expensive ingredients from the far corners of the empire, but also a trained, literate staff with access to a well-equipped kitchen, something beyond the means of the rural population; he cautions, though, that the agricultural workers perhaps enjoyed more varied fare than one would imagine, being able to draw on wild edibles to flavor their pottages (1985).

This gulf between what the mass of people in the ancient world ate and the foods enjoyed by the aristocratic, military, and commercial elite was not only a distinction based on variety or elaborate preparation, though these elements were fundamental: there was also distinction based on quality. Inhabitants of the Roman empire used a fish-based sauce called *garum* as a condiment. The rich enjoyed the best *garum*, which was the liquid ladled off the mass of macerated, salted fish innards used for production. The middle class used a pressing of what was left over, while the poor had to make do with the remains after pressing. While *garum* was used by the whole society, only the best *garum* was used in Roman patrician households’ kitchens (Curtis 1983). Given the preponderance of writers from the upper class, it is hard to determine to what extent the Roman plebeians saw these culinary divisions as an acceptable part of the correct rules of behavior.

Religious and Culinary Boundaries

Dietary norms, both proscriptions and prescriptions, function as outer boundary markers for the range of behavior which was considered ethical; certain foods were either *de rigueur* in certain situations or taboo in others, specifying correct relationships between person and their peers, their god(s), and their rulers. Culinary do’s and don’ts, though seemingly arbitrary, had the function of maintaining boundaries between one religious group and another, especially in areas like the eastern Mediterranean where the available foods were the same. By prescribing certain food practices – the use of unleavened bread for the Passover celebration – and proscribing others

(like pork), Judaism was able to maintain its religious-cultural integrity in the face of competition from both polytheists and the other two major monotheistic religions, Islam and Christianity. As Rosenberger points out, religious injunctions on eating habits created artificial divisions between the realms of the licit and illicit, the pure and the impure (1999).

This religious delimiting of cuisine was both more important and more difficult as those that followed Islam, Christianity, and Judaism expanded their territorial range. How can one define, for example, “Arab cuisine” when the Arab empire was an extremely heterogeneous one, with dramatic differences in climate (and therefore flora and fauna)? Previous cultural traditions of conquered peoples also formed a substratum of foodways that the new imperial cuisine had to compete with, and ecological and other practical constraints forced compromises on “ethical food.”

Are these culinary boundaries simply arbitrary or do they derive from more basic infrastructural limitations? Materialist anthropologist Marvin Harris saw food taboos and traditions as higher-order manifestations of environmental factors that affected the processes of food production. Discussing the shared Judeo-Islamic prohibition on pork, Harris suggests that it was the result of a very conscious cost-benefit analysis of zootechnical practices in the Middle East (1985). Whereas goats, cows, and sheep were ruminants and could transform high-cellulose plants into protein (meat and milk), pigs competed with humans for food, and in the deforested Eastern Mediterranean (home of both Islam and Judaism), the pig was not worth raising: to the contrary, it was a threat to a fragile ecosystem. Thus, culinary conventions – the taboo on pork – were simply the tip of the iceberg of ecological problems, a solution to an environmental risk. Whatever the ultimate cause of this taboo, the prohibition on eating swine is not seen as arbitrary, even by those Muslims and Jews who accept the materialist origin but continue to observe it. That even those who ascribe its origin to necessity accept the limitation demonstrates that this culinary proscription is an ethical boundary, one of the many that demarcate the category “cuisine.”

The proscription and prescription of certain foods in Europe were also strongly influenced by medical theory; from the end of the eleventh century until well into the seventeenth, the humoral theories of Galen and Hippocrates dominated thinking about eating. Digestion was seen as a form of cooking, and proper digestion required the maintenance of humoral equilibrium. Hot, dry foods like cured meats had to be balanced with cold, wet foods like fruit. Class was another variable in this medical system: Cuisine was a contested cultural area where the upper class perennially sought to impose an ethical explanation for class-related dietary differences on the lower social orders. Foods that were higher up in the Great Chain of Being (birds of prey, fruit which hung from trees) were not only healthier for those higher up in the social hierarchy, but also more appropriate; “low” foods like beans and tubers were consistent with the more hardy stomachs of peasants (Grieco 1999), and it was quite literally cosmically “right” that they should eat them. Montanari (2010) describes an early seventeenth-century tale by Giulio Cesare Croce, in which a commoner, Bertolodo, switches places with the king. Bertolodo at first enjoys his new-found position and all the rich food that accompanies it, but the inappropriate food ultimately sickens him, and he dies asking his doctors for “a pot of beans and an onion, and turnips cooked under the ashes.” The message is clear: commoners should stay in their cosmically appointed place, culinarily speaking.

Nationalism and National Cuisines

Nationalism is a product of European thought, and therefore a discussion of national cuisines necessarily begins with Europe. Though there was a mixing of Mediterranean and northern European foodways after the fall of the Roman empire and the migration of the Germanic tribes into southern and western Europe, medieval Europe had a relatively homogenous food culture, barring certain foods that grew only in certain areas, such as rye in the north and grapes in the south (Montanari 1999). Spices, integral to the cuisine of the elite and used in amounts that

would nauseate the modern diner, were a kind of conspicuous consumption used to show status. Schivelbusch gives the daily allowances of the king of Scotland when visiting Richard I of England: two pounds of pepper and four pounds of cinnamon (1992). The Roman church was an important culinary unifier: both the importance of the liturgical foods like wine, oil, and bread and injunctions about lean versus fat days provided a degree of continuity no matter where one traveled in Europe. This was, like the Muslim-Jewish taboo on pork, the culinary facet of a complex ethical system which included politics (the divine right of kings) and the market (the continuing ban, observed more in breach, on usury). More similar than different, cooking styles in Europe began to diverge from one another between the end of the Middle Ages and the middle of the nineteenth century, reflecting among other things the Catholic church's rapidly declining role in ethical decisions in Europe.

Among others, Mintz (1996) has argued that national cuisines were necessarily an invention, part of the same process of the invention of nations. Regional cuisines are defined by the ingredients available in a prescribed geographical area prepared in traditional ways. Haute cuisines – and by these Mintz means those available only to the social strata that have the means – are necessarily national and draw on regional cuisines. A haute cuisine is a complex field that draws on the dishes of a nation's regions and reveals itself by what it serves, especially ingredients that are out of season or otherwise difficult to come by, by the additional (and often quite elaborate) expert preparation required. This national cuisine depends on an elite to provide the demand for the trained cooks and expensive ingredients that it requires: in France, the site of one of the first codified “haute cuisines,” it was the king and his court that created that demand. This is not to say, however, that because there is income stratification, there will necessarily be distinctions between “common food” and “cuisine.” Goody's 1982 study of foodways in West Africa shows that, despite the existence of a socioeconomic hierarchy, food choices between businesspeople and day laborers can be almost identical.

The meaning of cuisine, the borders of the culinary territory that it delimits, has changed substantially since the end of World War II. This was partly due to an acceleration of the trend, which begun in the middle of the nineteenth century, whereby the development of large-scale food industries slowed and then reversed the differentiation of cuisines in Europe and around the world (Flandrin 1999). This was not a uniform process, however, as decolonialization created new nation-states, whose indigenous ruling elite then “invented” national cuisines, mainly drawing on formerly scorned local foods (Wilk 1999). In Wilk's example, the high ethical price put on supporting and in effect creating “Belizean cuisine” completely changes the semantic-moral value of indigenous foods. Patriotism (an ethical imperative during decolonialization) was equated in Belize with love for one's country as well as one's country's food.

As Priscilla Ferguson reminds us, despite the seeming naturalness of French cuisine as a kind of standard against which other cuisines are judged, it too is the result of culinary traditions being selected as a vehicle for national identity (2004). To paraphrase linguist Max Weinreich, if a language is a dialect with an army, perhaps a cuisine is cookery with a cookbook. Perhaps far more than anything else, a source of codification and creation of national cuisines has been driven ahead by the printing press, the standardization of languages, and the expansion of the number of people who can then afford books (about cuisine) in these languages. Arjun Appadurai has suggested that the previously inexistent concept of “Indian cuisine” springs from a sudden explosion of “Indian” cookbooks, which appeared in response to a mobile and upwardly mobile middle class in India; this new middle class was eager to both replicate the cooking of its youth and show off high-status regional dishes (1988).

The Refined and the Raw

The post-WWII United States was the avatar of highly processed cuisines. Advanced chemical techniques used space-age technology to make

cuisine not out of food but of food constituents: corn went from being an ingredient in soups to a raw material for insulation, batteries, and cosmetics as well as (almost incidentally) cake mixes, chewing gum, and margarine (Pollan 2006). Refined cuisine was based on refined food products, those that were processed, broken down, and recombined. 1968 was the beginning of the current reaction to this modernist cuisine.

Warren Belasco has ably collected all of the threads of ideology that contributed to the counterculture's attack on "corporate cuisine" (2007). The widespread student revolt of the late 1960s and early 1970s launched a new look at cuisine as well. Critiques of modern cuisine bemoaned the corporate nature of much food production and the consequent artificiality of the product. If the personal was political, nothing could be more of a statement against the establishment than three meals a day eaten "outside of the system." Belasco describes earnest food revolutionaries focusing on the production phase, seeking out products that were more "natural" and even attempting, during the back-to-the-land movement, to become autarchic. Despite the widespread failure of communal food production by hippies, the counterculture inspired new cuisines that for the first time rejected ethnic, religious, or national limits for cuisine, but instead tried to define the boundaries of the pure and impure with ethical standards.

While modern vegetarianism began in England in 1847 and vegetarianism has been a way of life for millions of people on the Indian subcontinent for centuries, its spread in the West began with the ethical counterculture revolt. Especially influential was the book *Diet For A Small Planet*, in which Francis Moore Lappé explained that the cause of hunger in the Third World was not a lack of food production, but rather maldistribution (1971). Whereas cattle and pigs, Americans' two main sources of animal protein, had previously been raised on grass or (in the case of the pigs) food scraps, new concentrated animal feeding operations (CAFOs) were replacing this feed with cereals, mainly mais. Lappé discovered that it took roughly seven pounds of corn to make a pound of meat, an incredible waste of energy and food. For the first

time in America, in the 1970s, meat was pushed out of the circle of "cuisine," for vegetarians, not for religious reasons, but for ethical ones. In a twist on French gourmand Brillat-Savarin's famous aphorism, it was now possible to say, "Tell me what you *don't* eat, and I'll tell you who you are."

Ecological Cuisine

Many religious dietary laws have ethical components – Halal and Kosher laws insist on swift, painless slaughter of animals – but the new cuisines in the post-1968 world took this even further. The methods of food production were subjected to scrutiny to ensure the well-being not only of animals, but also of the people involved in production. Corporate farming was demonized even as it grew to be a larger and larger share of American food production as family farms declined in number. Whereas new varieties of seeds, combined with fossil fuel-derived pesticides and fertilizers, had been hailed as a revolution in the immediate postwar period (the so-called Green Revolution), organic production gained in popularity with consumers. Eschewing artificial fertilizers and pesticides, organic producers used ancient techniques for fertility maintenance and pest control (Pollan 2006). While organic cannot be considered a cuisine in the strictest sense – few consumers use only organic foods in their cooking – it was an ideal whose goals were not only better health for the individual (dietetics, as we have seen, has long been part of cuisine) but also for the environment.

An interesting example of how this critique of corporate control of food production and subsequent environmental degradation has been used to delimit cuisine is the punk movement. Whereas French structuralist anthropologist Claude Lévi-Strauss had created a conceptual scheme for food which had three interrelated poles – raw, cooked, and rotten – for comparing cuisines in industrialized and traditional societies (1975), punks' anti-corporate, anti-mainstream stance reinterpreted the meanings of that triad. Raw food (organic, local, even wild) becomes the most civilized, the food for inclusion in their cuisine. "Rotten," here

meaning not food gone bad but food that has been thrown out but subsequently “dumpster dived” by punks, is also included in punk cuisine; even “corporate food” can be transformed by time in a dumpster or even by the simple act of being stolen from for-profit supermarkets, especially upscale ones. This radical redefinition of cuisine (what is good to eat and what is not) is a marked break with pre-1968 systems which were based on more clearly defined religious, ethnic, and/or geographical markers (Clark 2004). Punk cuisine, which relies on an abstract ideology of “goodness,” can be contrasted with so-called molecular gastronomy, which affirms the primacy of science and supposed natural affinities in food chemistry to determine which combinations of foods are desirable (This 2006).

Another recent redefinition of cuisine is provided by the local (or “locavore”) movement. Again starting with a wider, ecological definition of “health” (of the planet as well as of the individual), locavores promote the consumption of food produced within a given geographical area, a “foodshed.” Despite critiques of this approach to greater food sustainability – that “local” is not clearly defined and that transportation is a rather small energy cost in a food’s total energetic budget (McWilliams 2010) – the local movement has led to a revaluation of forgotten local varieties and dishes as well as their appearance on menus in restaurants and tourist brochures promoting culinary tourism. This may, however, be yet another attempt to use food to create class distinction: with Wal-Mart making organic food available to the masses, local food (often more expensive) is simply an attempt to make up for the loss of distinction. Thus local becomes simply the most modern method for delimiting class boundaries by placing cuisine out of reach of “the commoners” (Potter 2010). The importance placed on local food seems to be inconsistent with the current enthusiasm for fair trade food products – primarily the former colonial goods like coffee, sugar, and tea – which are by definition from far away.

While haute cuisine – the complicated dishes of the French upper classes – sought social distance with distinction, the often-lauded cuisines of today

seem to be more democratic, in keeping with contemporary society’s rejection of the reinforcement of class divisions through ethical precepts. Indeed, local food or the *cucina povera* (“peasant fare”) in its search for the food that the poor of the past ate seems to be a sort of atonement for centuries of upper-class culinary snobbishness. Careful examinations of these supposed peasant foods reveal, however, that rather than a culinary appeal to ecumenicism, they are often invented tradition and simply a new, more subtle means of distinction. The so-called Mediterranean diet contains foods like extra-virgin olive oil and feta cheese which are too expensive for many to enjoy regularly, and given their Mediterranean origin, pose questions about fossil fuel use in their voyages towards wealthy enthusiasts in East Asia, Australia, and the Americas.

What is correct and just food behavior? This essay has attempted to show that the rules social groups construct and impose on their members regarding foods and eating are often a complex interplay of environmental, socioeconomic, and religious factors. These rules help define “right behavior” for the group’s members, thus forming and integral part of that group’s ethical system. An important goal of this entry is to describe the fluidity of these culinary-ethical norms across time and space.

Summary

This entry explores the cultural-material construction and social maintenance of the concept of “cuisine.” It begins with the transition from hunting and gathering and the implications for differentiation between classes and then discusses cuisine in the classical world. Thereafter the entry traces religious proscriptions and their ethical (or materialistic) background, followed by a brief look at cuisine in the medieval period. European (and extra-European) nationalism and the redrawing of cuisines’ boundaries along patriotic lines is the subject of the next section. The modernization of “industrial cuisine” and the ethical revolt against it, one which continues up to today, concludes the essay.

Introduction

Agriculture, like many human enterprises, is a product of many varying overlapping knowledge practices: intensive and perceptive firsthand observations; personal experiences and communal memory; reliance on trusted interpersonal and institutional testimony, given keen discriminating assessment of credibility; and skill knowledge and tacit knowledge of all sorts alongside leading-edge science and engineering in botany and zoology, biochemistry, genetics, nutrition, land management, ecology, and oceanic and atmospheric sciences.

Agriculture, like many human enterprises, is a product of both considerable self-reliance and intellectual interdependence. This rich, complicated balance of epistemic autonomy and dependency in practice raises epistemic and ethical issues concerning the nature of agricultural expertise and, specifically, implications for how claims and renunciations of expert authority affect social relationships and knowledge practices among agronomists, corporations, farmers, and the varied nonexpert publics to whom they provide food, fuels, building materials, and many other products.

An Overview of Epistemologies of Expertise

Expertise can be understood as a kind of epistemic attainment or a kind of social authority. Accordingly, different analyses of the nature, power, and problems of expertise consider its epistemic and social senses. Epistemologists and many other philosophers tend to emphasize its veritism. For example, in debates on the epistemology of peer disagreement, “expert” is operationalized straightforwardly as someone to whose opinion regarding some proposition in their domain of expertise one should totally defer (Elga 2007) or as someone more talented and informed than relative nonexperts (Weatherson 2007).

Alvin Goldman (2001) defends a veritistic account of expertise that distinguishes *skill* experts, unusually accomplished at certain skills, from *cognitive* or intellectual experts, who have an exemplary quantity or level of propositional knowledge of a domain and propensity to generate new knowledge in that domain. Goldman further distinguishes *reputational* experts, those regarded as experts, from *objective* or genuine experts, those who actually have the expertise whether or not their reputations match. Also noteworthy is his distinction between *weak* and *strong* senses of expertise. Weak cognitive expertise requires extensive knowledge of what Goldman considers secondary questions in a domain of expertise, concerning the existing arguments, theories, evidence, and researcher assessments of

evidence which bear on the primary questions of a field. Strong cognitive expertise, then, requires knowledge of both secondary and primary questions. So two practitioners well versed in the state of their field but defending divergent positions on the right answers to the primary questions in their field can both be experts in the weak sense, but at most only one can be an expert in the strong sense. Objective cognitive expertise for Goldman is largely but not entirely a matter of comparison: experts *as* experts must have more true and fewer false beliefs about their domains of expertise than most people do and, further, meet some non-comparative threshold of veritistic attainment. Goldman's third requirement is a propensity criterion, the capacity or disposition to correctly answer new questions emerging in one's field by drawing on the skill set and techniques constitutive of expertise. This propensity involves the ability to successfully apply knowledge of the field (and use data banks, relevant apparatuses, etc.) to address new questions; as such, the propensity criterion would seem to require some skill expertise even for cognitive experts. (Solomon (2009) and Coady (2012) offer critique and variations on Goldman's epistemology of expertise).

Critics of expertise such as Paul Feyerabend, Steve Fuller, and Raphael Sassower emphasize expertise as a matter of social reputation. For his part, Sassower (1993) associates expertise with postures of certainty and infallibility. The social role of modern scientists as experts is akin to ancient oracles, Sassower says: from their socially privileged position, experts tell the rest of us what to believe, and their lofty position allows the rest of us to believe certainty exists somewhere, and that we at least have indirect access to it. Feyerabend (1999), meanwhile, identifies experts with *specialists* who by their nature inhibit growth of scientific knowledge because they are ideologically wedded to conventional wisdom and so serve to keep unusual views from improving science. Feyerabend prefers generalists, *dilettantes*, who bring novelty or creativity into scientific conversations. (See Selinger (2003) for careful critique of Feyerabend's skepticism toward expertise). Critics of expertise are also troubled by the privileging of institutionalized

science over local or traditional agroecological knowledges, which are rarely accorded social reputations of epistemic authority in global market systems.

Sociologist of science Harry Collins writes extensively on expert/nonexpert relationships and the place of tacit knowledge in scientific expertise. In *The Golem* and *The Golem at Large*, Collins and Pinch (1993) characterize science as a kind of expertise and scientists as "craftspersons, the foremost experts in the ways of the natural world." Their aim is to articulate an alternative to the conception of science as certain knowledge; the portrait of scientists as experts with limited expertise is offered as a middle way between scientist as God and scientist as charlatan. Rather than trying to achieve some junior scientific expertise, Collins and Pinch advise non-experts engaging with scientists to cultivate an *expertise of everyday life*, akin to what people use in dealing with other sorts of experts, as when hiring a plumber. Collins continues to explore expertise in collaborative interdisciplinary projects under the umbrella of Studies in Expertise and Experience (SEE). Collins and Evans (2007) are relatively positive about expertise, a stance that finds criticism from scholars such as Jasanoff (2003) and Wynne (2003) less sanguine about expert/nonexpert relations in modern life. Collins proposes *interactional* expertise as a middle epistemic way between that of nonexperts and *contributory* expertise of full practitioners of a domain. Interactional experts can speak the language but not fully play the game; what distinguishes interactional experts and contributory experts are the latter's skills and abilities not captured by the body of propositional knowledge distinctive of the domain, which interactional experts can acquire (Collins 2004). Yet contributory experts' tacit knowledge does not mean epistemic independence. The expertise comes *in the doing* – the performance of essential practices, whether in the laboratory or the field – but it cannot be done without extending epistemic trust. Collins finds that successful acquiring tacit knowledge characteristic of a field requires new practitioners to be socialized into the relevant community of practitioners. The social nature of

science means that an expert does not operate without some degree of trust in other experts, whose agreement confirms that one has achieved competency in this expertise. (Selinger and Mix (2004) argue that Collins overemphasizes the importance of linguistic skill: contributory experts do not always describe their expert activities very well, and nonscientists can sometimes make original contributions too).

The conceptions of expertise in terms of reliability and social authority have been reflected by the role of experts in law. American legal models of expertise take reliability to be an important factor as evidenced by recent US Supreme Court decisions on the admissibility of expert witness testimony. Differentiating expert testimony from other testimony is its status as an admissible form of hearsay evidence; experts are witnesses who need not be eyewitnesses. Justice Blackmun argues for this, citing reliability. “Unlike an ordinary witness, see Rule 701, an expert is permitted wide latitude to offer opinions, including those not based on firsthand knowledge or observation. See Rules 702 and 703. Presumably, this relaxation of the usual requirement of firsthand knowledge... is premised on an assumption that the expert’s opinion will have a reliable basis in the knowledge and experience of his discipline” (Daubert 1993). Precedents and rules guiding admissible expert testimony in the US court system do not require expert witnesses to be independent of nor confirmed by other experts. *Frye vs. United States* (1923), long the guiding precedent in these matters, deemed admissible expert testimony to be that consistent with those practices generally accepted by the relevant expert community. This changed with *Daubert v. Merrell Dow Pharmaceuticals* (1993), however: the court ruled that *Frye* had been supplanted by legislation establishing Federal Rules of Evidence. According to the court’s interpretation in *Daubert* and subsequently in *Joiner* (1997) and *Kumho* (1999), the Rules admit all expert witness testimony that the trial judge deems to be reliable and relevant to the case at hand. The court allowed that reliability can be gauged by a variety of indicators: methodologies employed, error rates, peer review or journal publication of hypotheses

testified to, as well as acceptance by a relevant expert community. (Borenstein (2002), Haack (2005), and Brewer (2006) provide further philosophical discussion of legal expertise).

Worth special attention in reflecting on agricultural and food ethics is the murky status of moral expertise, of which both professional philosophers and the public tend to be wary. If expertise requires clear social authority, few if any secular figures enjoy unambiguous authority on morality. If the rational response to experts is deference, many are unsettled by such renouncement of moral autonomy. (Singer (1972), Driver (2004), and Archard (2011) offer contrasting arguments on the scope and possibility of ethics expertise).

Ethical Issues in Agricultural Expertise Ascription

The conceptual slippage among veritistic, reputational, and social-epistemic hybrid accounts of expertise opens space for various ethical issues of respect and recognition concerning agricultural knowledge and practices. Lisa Heldke (2006) argues that, in contemporary urban- and suburban-dominated US American culture, knowing about farming and other rural things is too often conceived as *stupid-making* knowledge. Perversely, a person is taken to be less knowledgeable overall – or less knowledgeable of “what matters” – for knowing about agriculture; correspondingly, ignorance of farming and rural practices may be flaunted as signaling properly organized epistemic priorities. See Berry (2002) and Carr and Kafalas (2009) for further discussions of how rural practices can be dismissively framed as *anti-knowledge*.

Related to the problem of so-called stupid-making knowledge is neglected or devalued knowledge: fields in which the possibility of expertise (as a social or epistemic achievement or both) is not even recognized because the field and its practitioners are socially marginalized. Wynne’s (1989) discussion of Cumbrian sheep farming after the Chernobyl disaster addresses just such an issue. The shepherds were assumed not to count as relevant experts, not because they

were especially bad practitioners of their field, but because sheep farming was overlooked as something requiring genuine expertise. Baars (2011) argues for urgency in integrating farmers as experienced innovative practitioners in research projects on organic agriculture. In general, greater recognition of practitioners' *know-how* as a legitimate form of agricultural knowledge alongside *know-that* expertise can be an ethical corrective for historical devaluation of rural knowledge. Wohlforth (2005) explores how subsistence hunters' ecological knowledge complements, complicates, and challenges climate scientists' field work in coastal Alaska. Carolan (2006a, b) argues that Iowa farmers have local knowledge deserving greater voice in the development of sustainable agriculture, applying the notions of contributory and interactional expertise to extend more credibility to small-scale farmers as marginalized knowers.

Failure to recognize expertise can constitute disrespect toward particular kinds of knowledge practices, but it can also constitute disrespect toward specific marginalized knowers, even in well-recognized fields of expertise. As Karen Jones (2002) aptly puts it, "testifiers who belong to 'suspect' social groups and who are bearers of strange tales can thus suffer a double disadvantage [...] being doubly deauthorized as knowers on account of who they are and what they claim to know." Miranda Fricker (1998, 2007) draws attention to credibility gaps between testifiers' actual rational authority in a field and the social power that recipients ascribe their testimony in that field. Testifiers enjoying more social power than their knowledge really warrant (perhaps due to accent, comportment, social privilege, or hyperextension of expertise) are said to enjoy *credibility excesses*. By contrast, testifiers whose rational authority warrants greater social power than others grant them (perhaps due to accent, comportment, or negative social stereotypes) suffer *credibility deficits*. In some cases, credibility deficits may be innocent, free of morally culpability, but in circumstances when credibility deficits derive from negative identity-prejudicial stereotypes, Fricker argues, a knower suffers a distinctive kind of wrong, *testimonial injustice*. The

agricultural expertise of women is frequently subject to gender-based credibility deficits (cf. Code 1991; Feldman and Welsh 1995; Jewitt 2000). Testimonial injustice may also apply to aforementioned small-scale organic and sustainable farmers (Carolan 2006a; Baars 2011).

Social neglect of marginalized people's agricultural knowledge can be both disrespectful toward knowers and disadvantageous for (dis)trusting others by impeding social exchange of valuable knowledge. Another form of injustice in knowledge ascription arises when marginalized people's knowledge is valued, and so appropriated, and yet their expertise continues to be suppressed and ignored. In such cases, marginalized peoples' knowledge is incredibly beneficial (financially, nutritionally, etc.) for others, yet these knowers fail to receive the social-epistemic recognition they deserve. Vandana Shiva (1999, 2000) argues against "bio-piracy" as this sort of ethical-epistemic injustice. Traditional agroecological knowledge once wholly ignored or devalued by Western agribusiness is now eagerly taken up, while intellectual credit and socio-ecological context are denied or downplayed. Yet respect means recognition of agricultural practitioners *as knowers*, not just passive sources of agroecological information for expert co-optation.

Finally, one should not ignore ethical implications attendant to the problem of *unwarranted* or *unwanted* expertise ascription. Solomon (2009) explores how public participation in biological research alternately can be understood in terms of stakeholder participation or recognition of neglected lay expertise (see also Jordan et al. 2005). Some knowledgeable individuals and communities reject "expert" titles as misleading or silencing; some practitioners take pretension to expertise to involve claims of certainty, or epistemic independence, or articulated propositional knowledge that they may not ascribe themselves, though they may know quite a lot. Jewitt (2000) cautions against overestimating women's agroecological expertise in policy analyses of women's roles in development in rural India, on the grounds that claims of expertise do not actually precipitate their greater epistemic and social

empowerment. Regarding the deep divide in contemporary American agriculture between industrial agribusiness and sustainable farming, Thompson (2001) argues against the assimilation of the latter as a specialized variety of the former. Such co-optation might make for savvy agribusiness, but on Thompson's agrarian philosophy, it would be a genuine loss, not a success in the recognition of sustainable farming as a kind of socially authoritative industrialized agricultural expertise.

Ethical Issues for Agricultural Expertise and Public Trust

Annette Baier (1986) offers a general moral test for healthy trust relationships applicable to agricultural expert/public relations. Her *expressibility test* holds that "to the extent that what the trusted relies on for the continuance of the trust relation is something which, once realized by the truster, is likely to lead to (increased) abuse of trust, and eventually to destabilization and destruction of the relation, the trust is morally corrupt. . . A trust relationship is morally bad to the extent that either party relies on qualities in the other which would be weakened by the knowledge that the other relies on them" (Baier 1986). Here we might emphasize the potential for expert exploitation given epistemic asymmetry. When experts depend on public lack of expertise in order to promote their favored policies, they fail Baier's test. When experts rely on public ignorance of the range of expert opinions on a disputed issue or rely on public ignorance of their tenuous credibility among other experts, the attendant public trust is corrupted.

Assessments and assumption of risk raise specific ethical issues for agricultural expertise and public trust. Heather Douglas (2003) argues that scientists (like others) have general moral duties against *recklessness* and *negligence*, both of which involve wrong action in the face of risk to self and others. The moral issue here concerns not the assumption of risk itself, without which science and engineering are impossible, but the *level* of risk and the fact that nonexpert publics are exposed to risk without their awareness or

consent. The use of pesticides and herbicides and the planting of transgenic crops (see Lacey 2005) are contexts in which farmers and other agricultural experts must consider the risks and rewards of practices that might affect communities locally, globally, and intergenerationally. Given such extensive vulnerability, experts also must consider whether and how they are socially and morally *authorized* to act on such communities' behalf.

So public trust and distrust in agribusiness raise serious challenges for agricultural experts. To that end, John Hardwig's ethics of expertise (1994) can be instructive. Hardwig outlines the problem in terms of ethical guidelines for four groups: individual experts, expert communities, nonexperts relying on experts, and society at large. The organizing priority is the recognition of epistemic and practical interdependency among experts and between experts and lay publics, remembering that those experts in one field are nonexperts in others. One notable maxim Hardwig identifies for experts is to tell the truth according to one's professional judgment, even when this is not what one's employers or others in power may want to hear. Scientists and engineers employed by multinational agribusinesses such as Monsanto or Cargill are likely to face this challenge of ethical expertise in specific and difficult ways. Attendant to this advice is the recognition of our inevitable propensity to rationalize: as such, reflective experts anticipate the temptation to believe and practice what employers and those in power prefer and work to counteract this tendency in themselves and fellow experts.

In doing their part to foster morally healthy public trust among farmers and consumers, agronomists and practitioners, agribusiness, and public, trustworthy agricultural experts offer testimony and do their work in ways that are not only reliable and transparent but also responsive to the fact of societal dependency on agriculture. Even experts are epistemically interdependent, and many farmers' and other practitioners' eco-agricultural knowledge fails to be accorded the social reputation of expertise: therefore, trustworthy agricultural experts must also actually recognize, engage, and partner with knowledgeable practitioners across cultures or traditions whose knowledge or

credibility as knowers has been neglected. Interactional experts such as government officials and journalists for their part might attend to their duties of fostering public understanding and providing external constraint and validation to expert practitioners. Ethics of agricultural expertise also calls upon nonexpert publics to practice *responsible trust*: to appreciate the uncertainty inherent to actual scientific practice, for example, and not to ascribe expertise in unwarranted or unwanted ways, nor to extend undue deference. (See Shrader-Frechette (2011) on lay responsibilities in (dis)trusting scientists and Kitcher (2003) and Elliott (2011) for further general discussion of the ethics of scientific expertise).

There is increasing recognition among agricultural and environmental ethicists of the value of nonexpert direct participation in eco-agricultural projects, which foster public understanding as well as public trust. Light (2006), for example, advocates for public-expert collaborations in environmental restoration work: “public participation does not mean that expertise should be abandoned in restorations; it just means that whenever possible, restorations are better when experts guide voluntary restorationists.” Community-supported agriculture and community gardens likewise suggest a potential democratization of agricultural expertise in which agroecological intellectual and material labor is performed (and the fruits of that labor harvested) collaboratively across epistemic and social differences.

Summary

Agriculture is built on many kinds of knowledge and practices: some skill based, some theoretical, some tacit, some explicitly articulated, some recognized as expertise, and others not. Some people who work in agriculture are granted social authority as experts, and others not, due to various more and less justifiable (and ethically defensible) factors, such as lack of sufficient knowledge in the field, credibility gaps, social ignorance of their knowledge, social devaluation of their knowledge, or that “expert” fails to capture their specific agricultural knowledge. Given pervasive social dependence on farmers, agribusiness, and

other producers of agricultural knowledge and crops, continued development of ethics of agricultural expertise is a matter of practical importance and certainly one in which people with contributory and interactional expertise of all kinds should have a voice.

Introduction

Governments have extraterritorial obligations regarding the right to food. In an increasingly

globalized world, activities of both state and non-state actors can have impacts well beyond national borders: hence, defining the parameters of extraterritorial obligations as a legal concept has become ever more important. Recent years have seen a growing consensus over the scope and substance of these obligations, including with respect to the right to food.

This contribution will define and discuss the concept of extraterritorial obligations and then apply it to the right to food in particular.

Extraterritorial Obligations of States

Definition and References in International Human Rights Law

Although the universal character of human rights, as well as the requirement of nondiscrimination attached to their realization, has always been clear, states traditionally have viewed their human rights obligations as limited to the people within their territories. This stance has led to a gap within human rights protection, apparent in a number of international processes. In effect, in times of globalization, the enjoyment of rights – especially economic, social, and cultural – is increasingly put at risk by the actions of transnational corporations, as well as of foreign states and intergovernmental organizations. Thus, focusing on the extraterritorial obligations of states can provide the missing link that will prevent such actors from escaping accountability for their unlawful actions or omissions that have negative impacts on human rights abroad, including those affecting people's access to food and other essential resources.

The extraterritorial obligations that international human rights law places on states require them to take certain actions, and refrain from taking others, either within or beyond their territories, that affect human rights beyond their borders. In addition, states must assist in the realization of human rights globally, through international assistance and cooperation. Thus, state obligations to respect, protect, and fulfill human rights have an extraterritorial dimension (ETO 2011, pp. II 8–9).

Extraterritorial obligations are implied in a number of international human rights instruments. Dating back to the advent of the modern international human rights regime, the extraterritorial nature of state duties were incorporated into the Universal Declaration of Human Rights, which notes in article 22 that “[e]veryone (...) is entitled to realization, through national effort and international co-operation and in accordance with the organization and resources of each State, of the economic, social and cultural rights indispensable for his dignity and the free development of his personality.” Subsequently, the International Covenant on Economic, Social and Cultural Rights (ICESCR 1966), a legally binding document, elaborated in article 2 on what such international cooperation entails: “Each State Party to the present Covenant undertakes to take steps, individually and through international assistance and co-operation, especially economic and technical, to the maximum of its available resources, with a view to achieving progressively the full realization of the rights recognized in the present Covenant by all appropriate means, including particularly the adoption of legislative measures.” The need for international cooperation in realizing specific human rights has been stated in other international instruments as well, including the Convention on the Rights of Persons with Disabilities (Art. 32) and the Convention on the Rights of the Child (Art. 4 and 24).

The Maastricht Principles on Extraterritorial Obligations of States in the Area of Economic, Social and Cultural Rights

Although human rights instruments explicitly mention international cooperation, the normative framework on human rights obligations that apply beyond national borders has been slow to emerge and consolidate. For many years, extraterritorial obligations were poorly developed, in part since they refer to obligations and responsibilities that extend to the sensitive political space situated beyond state boundaries (Langford et al. 2013).

However, as the international community witnessed the substantial impacts of state and non-state actors outside of their (home) territories, increased economic globalization and linkages

lent growing importance to developing a more robust understanding of the parameters of extraterritorial obligations. In this context, a network of civil society organizations and academics set up the ETO Consortium with the aim of clarifying the extraterritorial obligations of states, in particular with respect to economic, social, and cultural rights. In September 2011, a group of 40 international law experts adopted a set of principles called the Maastricht Principles on Extraterritorial Obligations of States in the Area of Economic, Social and Cultural Rights (ETO 2011).

The Maastricht Principles note that all states “have obligations to respect, protect and fulfill human rights, including civil, cultural, economic, political and social rights, both within their territories and extraterritorially.” They describe two types of extraterritorial obligations: “obligations relating to the acts and omissions of a state, within or beyond its territory, that have effects on the enjoyment of human rights outside of that state’s territory; and (...) obligations of a global character that are set out in the Charter of the United Nations and human rights instruments to take action, separately, and jointly through international cooperation, to realize human rights universally.” These obligations do not mean that states are responsible for the realization of all human rights throughout the world. Rather, a state has extraterritorial human rights obligations in three situations: (i) when it exercises authority or effective control, regardless of whether such control is exercised in accordance with international law; (ii) when its acts or omissions cause foreseeable effects on the enjoyment of human rights, within or outside its territory; and (iii) when it is capable of exercising decisive influence or of taking measures through its executive, legislative, or judicial branches to realize these rights extraterritorially, in accordance with international law, be it acting separately or jointly (ETO 2011).

Therefore, extraterritoriality applies to the traditional obligations of states to respect, protect, and fulfill human rights. In this context, the obligation to respect requires that states refrain from any policy or action likely to hinder the realization of economic, social, and cultural rights in other countries. The obligation to protect compels states to ensure that third-party actors that are under its

control, for example, domestically based transnational corporations, respect human rights abroad. The obligation to protect thus includes the obligation to regulate the behavior of such actors. Finally, states have the obligation to support other countries in their fulfillment of human rights obligations.

The Maastricht Principles are not legally binding and have not been adopted by governments. Yet they highlight a growing consensus that all states have extraterritorial obligations to respect, protect, and fulfill economic, social, and cultural rights (Langford et al. 2013). Since their release, extraterritorial obligations have been referenced in UN Special Procedures reports, such as the Guiding Principles on Extreme Poverty and Human Rights, which were prepared by the UN Special Rapporteur on Extreme Poverty, adopted by the UN Human Rights Council and noted with appreciation in a UN General Assembly resolution. Those guiding principles articulate extraterritorial obligations of international assistance and cooperation, as well as state duties to “prevent and protect against human rights abuse committed by non-state actors, including business enterprises, which they are in a position to regulate. (. . .)” (ETO 2011).

How Extraterritorial Obligations Apply to the Right to Food

The Right to Food and Extraterritorial Obligations in International Law

The extraterritorial obligations of states apply to the right to food. The right to food is codified in the International Covenant on Economic, Social and Cultural Rights, which also sets forth requirements for international cooperation. Similarly, the Rome Declaration on World Food Security also emphasized that the “multifaceted character of food security” required “concerted national action, and effective international efforts to supplement and reinforce national action” (World Food Summit 1996).

In 1999, the UN Committee on Economic, Social and Cultural Rights explicitly elaborated on this obligation, noting in its General Comment No. 12 on the right to food that “In the spirit of

article 56 of the Charter of the United Nations, the specific provisions contained in articles 11, 2.1, and 23 of the Covenant and the Rome Declaration of the World Food Summit, states parties should recognize the essential role of international cooperation and comply with their commitment to take joint and separate action to achieve the full realization of the right to adequate food. In implementing this commitment, states parties should take steps to respect the enjoyment of the right to food in other countries, to protect that right, to facilitate access to food and to provide the necessary aid when required” (Committee on Economic, Social and Cultural Rights 1999).

More recently, a subsidiary body of the Committee on World Food Security drafted Voluntary Guidelines that provide further guidance on how to implement the right to food. The guidelines encourage policies fostering an enabling environment, assistance, and cooperation, and cover international measures, actions, and commitments (FAO, Committee on World Food Security 2005). These guidelines thus stress that programs of aid and technical assistance, as well as trade, finance, and investment policies, need to be aligned with human rights and the right to food.

The Right to Food and Its Extraterritorial Dimensions: Illustrations

Illustrations of how extraterritorial obligations of states apply to the right to food abound, ranging from states’ public policies to the activities of private parties.

For example, in order to comply with their obligation to respect the right to food in its extraterritorial dimensions, states should refrain “from food embargoes or similar measures which endanger conditions for food production and access to food in other countries” (Committee on Economic, Social and Cultural Rights 1999, para. 37) and from supporting states that use food as a political tool or that blockade food deliveries for political reasons (*ibidem*). In addition, states should avoid discriminatory practices when providing food aid in foreign states (Skogly 2007, p. 352).

Agricultural subsidies in the North aimed at the structural overproduction and exportation of raw agricultural products to the South may also violate

states' obligations to respect the right to food. Thus, states should establish their policies of subsidies and market access in ways that do not threaten livelihoods of people in other countries, particularly in developing countries where alternative livelihoods for those affected are more limited than in wealthier countries and where systems of social protection are restricted or nonexistent (*ibidem*). Examples of harmful policies are the subsidies that were paid by the US government to a restricted number of cotton farms, particularly in the decade following 1995. They caused the world price of cotton to fall sharply, which in turn had negative consequences for West African producer countries, decreasing the market share for small-scale cotton farmers especially in Benin, Burkina Faso, Chad, and Mali. By reducing the income of the small-scale farmers and their national governments, the US subsidies undermined a series of rights, including the right to food, abroad (Skogly 2007, p. 353).

Another instance of potential state failure to respect and protect the right to food extraterritorially is found in transnational land deals, which have increased as countries and investors have sought to expand food and agro-fuels production abroad. These deals are frequently for large tracts of land on which farmers or others previously relied for food production or access to productive resources. However, without protected land rights, land users may face evictions and loss of access to productive resources, thereby jeopardizing the realization of their right to food. When a foreign government or its related entity undertakes this type of transaction, it may result in the government's failure to respect the right to food in another territory. When these transactions are conducted by private actors, such as agribusinesses or investment companies, the deal may imply the home government's failure to protect the right to food by not regulating such actors appropriately.

One final example relates to financial speculation on food prices by the banking sector, a practice that is potentially harmful to the right to food at the global level. Since around 2005, markets for several agricultural commodities have witnessed rapid price increases and higher volatility, which

severely affected the right to food in poor, net food-importing countries. While there are multiple reasons for these market trends, excessive speculation in agricultural commodities derivatives by investors may have significantly contributed to worsen market volatility. States, which already regulate the financial sector, should consider whether their obligation to protect the right to food extraterritorially requires stronger regulations that mitigate commodity price volatility, thereby helping to prevent future global food price crises.

With regard to these different examples, in accordance with Maastricht Principles 19–22, states should refrain from any action that would impede the enjoyment of economic, social, and cultural rights, including by those living outside of their borders. Moreover, the obligation of states to protect human rights includes their duties to regulate non-state actors, as required by Principles 23–27. Thus, they should regulate transnational companies involved in practices such as transnational land acquisitions or leases when they are implemented in ways that violate the human rights of the local communities. Finally, Principles 28–35 request states to create an environment that enables the fulfillment of human rights, including the right to food, through international cooperation.

Conclusion

In the context of globalization, the traditional view of territorial limitations on state obligations leads to significant gaps in human rights protection. These gaps can affect the enjoyment of the right to food and more generally access of people to essential resources. This is particularly true as challenges have grown, produced by factors such as the weak regulation of transnational corporations; the lack of accountability of intergovernmental organizations, including international financial institutions; the deficient application of human rights law to investment and trade treaties, policies, and disputes; and the insufficient implementation of obligations to protect and fulfill human rights abroad through international cooperation and development assistance (ETO 2011). A few of these obstacles were

illustrated above in respect of the right to food, namely, harmful agricultural subsidies, transnational land deals, and financial speculation on agricultural products.

In recent years, increasing attention has been paid to the obligations that states have to protect, respect, and fulfill human rights beyond their own territories. The Maastricht Principles, adopted by a number of international legal experts, present a particularly useful effort to develop the normative content of the extraterritorial nature of human rights obligations, clarifying when extraterritorial obligations arise and what those obligations entail.

Moving forward, the development of direct human rights obligations of non-state actors – such as transnational companies and international organizations – could be further explored as an additional way to address accountability gaps. While the UN “Protect, Respect and Remedy” framework for business and human rights – which has been widely embraced by governments, corporations, and other stakeholders – asserts that businesses have responsibilities to respect human rights, rather than obligations, there has been increasing consideration of whether businesses also have obligations regarding human rights; indeed, some scholars argue that such obligations already exist. Since corporations and other non-state actors have increasing influence and power, developing corresponding obligations could enhance their accountability, possibly by identifying them as duty-bearers and designing responsibility mechanisms at the international level.

Summary

States have extraterritorial obligations regarding the right to food. States must ensure that any of their acts or omissions, either within or beyond their borders, that may affect the enjoyment of the right to food beyond their own territories, are undertaken in a way that respects or protects that

right. In addition, states must act proactively to assist in the progressive realization of the fulfillment of the right to food outside of their own territories.

Fair Trade in Food and Agricultural Products

Neal H. Hooker

John Glenn School of Public Affairs, The Ohio State University, Columbus, OH, USA

Synonyms

[Development](#); [Food labels](#); [International trade](#)

Introduction

The value, variety, and source of fair trade food and agricultural products have grown significantly over the past few years. In 2010, global retail sales topped \$5.8 billion, a 5-year compound annual growth rate of nearly 30%. The USA accounted for more than \$21 million in 2011, yet remains relatively underdeveloped compared to key European nations (particularly the UK and Germany). The most commonly sold Fair Trade products at the consumer level are coffee, bananas, and chocolate (or rather cocoa as the primary Fair Trade ingredient), followed by tea, fresh fruit, and cane sugar. Flowers and plants, cotton, wine, and honey have also seen sales

growth over recent years. The top source nations in Latin America are Peru, Dominican Republic, Columbia, Honduras, and Mexico, and in Africa Kenya and Ethiopia generate significant sales. This entry introduces the reader to the scope of food Fair Trade and its documented impact. So informed the reader is encouraged to ask ethical questions about the merits of Fair Trade.

Scope: When, What, and Who?

Producers of raw agricultural imports from the developing “south” are challenged by geography, market structure, and size of operations. They are distant from their mostly developed northern consumers, their products pass through multiple stages of supply chains some with processing and value adding but not all, and generally these producers are small scale though often also horizontally aligned in cooperatives or marketing organizations. Fair Trade takes these three disadvantages and switches them around into advantages; place, exchange, and smallness are celebrated by traceability systems built around the notion of a fair price for farmers.

Under third-party international food quality certification systems that promote fair over free trade, agricultural producers generally receive higher compensation for their goods than if they were to sell them in open markets. Supply chains tend to be shorter (i.e., they involve few exchanges and fewer intermediaries), and consumers who purchase Fair Trade products typically pay more than for conventional substitutes. To be eligible to receive these increased prices, or more correctly assured minimum farm gate prices, agricultural producers in developing nations must adhere to Fair Trade sourcing standards managed by private third-party certification organizations. The elements of these production and processing criteria and nature of audits operated under these standards vary, based on the type of production, region, and third-party system/certification organization.

The Fairtrade Labelling Organizations International (FLO-I) serves as an umbrella organization for many certifiers, setting minimum standards for members and then owning and managing the

marketing of the Fairtrade™ claim which can be used on certified food products at the consumer level. Alternative Fair Trade certification systems exist, some adding on elements other than a fair price such as organic and some choosing other sourcing, supply chain, or processing standards such as requiring cooperative membership, social and environmental criteria, or minimum content levels for multi-ingredient foods. Certain producers may choose to comply with one Fair Trade standard, while others need to adopt several systems (not always harmonized in nature) if they are active in multiple supply chains. Producers can still usually sell products into the conventional channels if prices or other market conditions are preferable. Thus Fair Trade certification acts as a price risk management tool.

Fair Trade USA is the leading third-party certifier in North America and was a member of FLO-I until 2012. Fair Trade USA chose to adopt standards that differ to FLO-I in two key dimensions: the labeling and marketing of multi-ingredient products and inclusion of eligibility into the program for producers not in a cooperative. This strategy raises interesting ethical questions, including is it “better” to provide market opportunities to a larger number of producers, even if the standard is “lower”? and do consumers distinguish between the various levels of Fair Trade claims? Other key third-party certification systems, each based in Europe and including various environmental criteria, are Ecocert and IMO.

Does Fair Trade Make a Difference?

Several case studies, many concentrating on coffee production, have explored the benefits of Fair Trade on communities and individuals. The most comprehensive review of a Fair Trade system is presented by Nelson and Pound (2009) who assess the impacts of the FLO-I/Fairtrade™ standard. Their literature review of some 33 empirical published case studies suggests producers certified under this standard do receive higher returns and more stable incomes compared to those selling into conventional markets. The authors report strong evidence of social benefits in producing communities too. A lack of

quantitative evidence remains about the role of other Fair Trade standards, environmental/sustainability metrics, the impact on hired labor and differences in more diverse production systems (crops and regions).

As with many Corporate Social Responsibility (CSR) efforts by food and retail firms it is important to separate the “promise” from the “practice” and question if a guaranteed minimum price at one point in a supply chain actually changes anything? Indeed, it is fair to ask what behavior is the particular Fair Trade certification system trying to change – consumers, firms, and/or stakeholders? The management of differences between the various Fair Trade standards has not been elevated to a food policy discussion anywhere globally. Thus it is unlikely that significant market distortions or externalities exist (Arnould et al. 2009). Labeling claims of Fair Trade are generally governed like any other – that is they must be “true” but how impactful is not addressed by any government agency.

Ethical Questions

Regional consumer differences in interest, understanding, and willingness to pay a premium price for Fair Trade food appear to exist. This said, it should not be surprising that, like other CSR issues (e.g., organic food), various distinct consumer market segments exist. There is not just one type of Fair Trade customers (Brown 2013). Certain European and North American consumers value Fair Trade products but do not always understand the nuances of the various standards and claims. This leads to further questions surrounding the role of education: who should inform consumers and other stakeholders about these certification systems?

An important aspect of Fair Trade certification systems is the guaranteed minimum (farm gate) price. How far above a “free” trade (international market) price should this premium lie? How are production, processing, and distribution differences (such as environmental protection, social investments, and market development) “valued” within this pricing model? As Fair Trade certification systems develop to include a greater variety

of (multi-ingredient) foods and more hired labor production systems over individual farmers or cooperatives, how does the notion of a living or “fair” wage differ to that of a fair price? Costs of living differ by country, and then within countries living costs differ regionally. How can these nuances be identified and rewarded through a Fair Trade system?

Some critics of Fair Trade suggest more harm than good results from certain systems particularly if money is merely redistributed from other planned charitable giving at an institutional, government or consumer level. The proportion of any consumer price premium returned to the poorest farmers is argued to be too small to be impactful, particularly when compared to the costs of compliance with Fair Trade standards (Griffiths 2012). Questionable political motives may also underlie the targeted development activity embedded within individual Fair Trade certification systems.

Clearly, there are several inherent ethical issues captured within the increasing use and diversity of Fair Trade claims. Caution is recommended in the interpretation of these standards. Transparency should be enhanced else consumers may question the merits of such sourcing certifications and move their dollars or euros on to other causes.

Summary

As the value, variety, and source of food Fair Trade products increase, so a more complex set of ethical questions become more prevalent and pressing. Third-party certification standards offer a range of criteria, use different audit procedures, and have idiosyncratic approaches to market development. These differences might gain the attention of food policy makers in the future particularly if market share, consumer confusion or political pressure from key stakeholder groups reaches a critical point.

Introduction

Fake meat, also known as faux meat, imitation meat, mock meat, meat alternative, or meat

substitute, is a food designed to approximate the culinary qualities of flavor, texture, and appearance of different types of meat. Many fake meats are made from gluten (seitan) or soybeans (tofu and tempeh). Fake meat is different from clean meat. Clean meat, also known as cultured meat, lab-grown meat, in vitro meat, or synthetic meat, is muscle tissue grown in cell culture in a laboratory (Shapiro 2018). Clean meat is produced using many of the same tissue engineering techniques used in regenerative medicine. Carnal meat, in contrast, is flesh taken from the corpse of an animal. Fake meat is a meatless substitute for both carnal meat and clean meat.

Advantages of Fake Meat

Reasons that commend fake meat over carnal meat can be grouped into six groups of considerations. These considerations appeal to (1) health benefits, (2) reducing environmental harms, (3) conserving agricultural resources and energy to feed more people, (4) rejecting the patriarchy implicated in meat, (5) moral consideration for nonhuman animals, and (6) religious or spiritual commitments.

Health Benefits

Vegetarian diets tend to be healthier than diets based on meat and animal fat. Meat-based diets are associated with higher rates of heart disease, atherosclerosis, high cholesterol, stroke, peptic ulcers, osteoporosis, kidney disease, colon cancer, lung cancer, breast cancer, uterine cancer, cervical cancer, and prostate cancer. People suffering from diabetes, angina, asthma, bladder disease, diverticulitis, gallbladder disease, hypertension, kidney stones, peptic ulcers, and rheumatoid arthritis have been shown to benefit from switching to vegetarian diets. Meat eaters risk serious and sometimes fatal food-borne illnesses (Stephens 1994). Thus, other dietary factors being equal, fake meat contributes to a healthier diet than carnal meat.

Reducing Environmental Harms

The global populations of chickens, cattle, pigs, and sheep continue to grow with the global human population. In 2011 the world's average stock of

chickens was almost 19 billion; there were 1.4 billion cattle, about 1 billion sheep, and nearly 1 billion pigs (Economist 2011). Industrial livestock production is a leading source of organic freshwater pollutants and nitrate groundwater pollutants. Cattle are major causes of soil compaction, erosion, and depletion of freshwater aquifers. Cattle are a leading cause of deforestation, desertification, habitat loss, and destruction of thousands of species of plants, insects, birds, reptiles, and mammals. Moreover, industrial livestock production consumes great amounts of nonrenewable energies (Stephens 1994). On one analysis, livestock and their by-products account for 51% of annual worldwide greenhouse gas emissions (Goodland and Anhang 2009). Consequently, livestock contribute considerably to global climate change. Concentrated animal feeding operations (CAFOs) are where an increasing percentage of the world's meat, milk, fish, and eggs are produced (Imhoff 2010). Therefore, the meat industrial complex is responsible, both directly and indirectly, for devastating, manifold, worldwide environmental harms. Compared to industrial meat, fake meat treads much more lightly on the planet.

Conserving Resources and Feeding More People

Breeding livestock and feeding them grain and soy in order to make meat is an extremely wasteful way of feeding people. Most of the calories and protein in the grain and soy fed to livestock is lost by cycling it through their bodies instead of consuming the grain and soy directly. Transforming grain and soy into fake meat requires some additional inputs, depending on the kind of fake meat product. Nonetheless, fake meat products are a more efficient means of making foods from grain and soy than are meat products. Citizens of affluent, developed nations consume far more meat per capita than citizens of developing nations. So, one can argue that those who lack enough to eat deserve basic food more than the wealthy deserve the unnecessary luxury of meat from CAFOs. Justice suggests that agricultural resources be distributed equitably in order to reduce unnecessary human suffering and death caused by malnutrition (Stephens 1994). Thus, fairness favors fake meat.

Meat and Patriarchy

Another argument for meat substitutes is that there is an intimate connection between meat and male dominance. Meat is exalted in our patriarchal culture. The male prerogative for meat is exhibited in the Bible in Leviticus 6, in the ancient Greek myth of Zeus and Metis, and in fairy tales that portray meat eating as the male's role. In societies with animal-based economies, men hunt, control meat distribution, and wield social power typically to dominate women. In many nontechnological societies, women are forbidden to eat meat. Violence against animals intersects with sexual violence against women. Anthropological, sociological, and historical studies illustrate that the oppression of women and other animals is interdependent. Twentieth-century meat textbooks proclaim that meat is a virile food. Our society equates vegetarianism with emasculation or femininity (Adams 1990). Consequently, to reject meat in cultures where meat is plentiful signals rejection of male control and violence. Adams concludes that feminism and vegetarianism ought to be embraced by members of our "meat is king" patriarchal culture in order to transform it from within (Stephens 1994). How effective the choice of fake meat is in achieving this goal will be addressed below.

Sparing Nonhuman Animals

Moral consideration for the animals bred into existence, made to suffer, and killed to make meat is a popular reason for adopting vegetarianism. The most influential arguments motivated by moral consideration for the animals themselves have been formulated in either utilitarian or deontological theories. Utilitarians object to the tremendous suffering animals experience in CAFOs and argue that meat is unnecessary for virtually everyone nearly everywhere (Singer 1990). Deontologists argue that animals are experiencing subjects of a life with inherent value, so we have a duty to treat them with respect, not as our resources. This duty includes boycotting all animal products, including meat (Regan 1983). The global meat industrial complex grievously harms and destroys billions of innocent animals every year. Therefore, replacing

murdered meat with a meatless substitute rights a real wrong.

Religious or Spiritual Purity

Some religions prohibit or discourage eating meat. Because of their commitment to the Dharmic concept of ahimsa (non-violence), Jains entirely abstain from meat, fish, and eggs. Vegetarianism is also common in Hinduism, Mahayana Buddhism, Sikhism, and Taoism. Some Christians argue for vegetarianism based on the eschatological hope in the promises and the providential work of God (Webb 2001). Others see vegetarianism as a logical expression of one's understanding of oneself as a Christian and one's exercise of one's Christian faith and discipleship (Largen 2009). The ancient Greek philosopher Pythagoras taught metempsychosis – the belief that the soul is immortal and transmigrates into other kinds of animals. Their spiritual beliefs led Pythagoreans to abstain from meat, fish, and beans. The third-century polymath Porphyry of Tyre, a follower of Plotinus, also believed in metempsychosis. In *On Abstinence from Animal Food*, Porphyry defends vegetarianism both for the purpose of freeing one's soul from the body and the sensible world and for ethical reasons. Thus, for thousands of years, vegetarianism has been adopted for the sake of spiritual purity. Fake meat can promote this goal.

Fake Meat and Carnism

Fake meat products are intended to persuade meat eaters to replace real meat with a meat substitute. Fake meat is designed to cater to those who have been conditioned to prefer meat. Companies that produce fake meat presume that foods that resemble meat are the norm for appetizing food. Carnism is the ideology that conditions people to eat certain animals (Joy 2010). Carnists regard meat as normal, natural, and necessary. Consequently, one could argue that purveyors of fake meat actually capitulate to and perpetuate carnism under the guise of supplanting it. For example, if someone is not a racist but at a glance appears to act like a racist, then there is a risk that racism could be reinforced. Similarly, if someone is a

vegan but at a glance appears to act like a carnist by eating what looks like meat but isn't, then this might subvert achieving the goal of veganism.

Do fake meat products reinforce carnism? Proponents of fake meat could deny this. They could argue that fake meat products give people the option of eating less carnal meat, or none at all. From this perspective fake meat could serve as a bridge to help meat eaters cross from carnism to vegetarianism. Once accustomed to eating a substitute for meat in her diet, the consumer may no longer miss carnal meat. The person for whom fake meat becomes the new normal may come to find the appearance and smell of carnal meat disgusting. Such a consumer could then explore vegan foods that do not resemble carnal meat at all. Perhaps an analog is the use of e-cigarettes to quit smoking tobacco. Vaping can serve as a bridge from tobacco use to vaping an e-liquid that contains nicotine to vaping an e-liquid entirely free of nicotine.

Ultimately, this argument for fake meat is pragmatic. You have to take consumers where they are. We live in a carnist society. Most meat eaters are only going to be persuaded to try meatless foods that closely resemble meat in appearance, texture, flavor, and perhaps smell as well. If carnism is both objectionable and ubiquitous, then the availability of substitutes for meat is a good thing. Meatless foods that resemble familiar meat products but are not ethically tainted give consumers real choices for their protein.

Summary

Fake meat products are healthier to eat than carnal meat. Fake meat products inflict far less damage on the environment than meat from CAFOs. Ecologically, fake meat requires fewer agricultural resources, less water, and less energy to produce than carnal meat. Using the same amount of agricultural inputs, fake meat feeds more people than carnal meat. Unlike carnal meat, fake meat harms no animals. Still, the advocate of veganism could object to making food that *looks* like it supports carnism. If fake meat is marketed with the slogan that "it tastes like meat, but is better for you," then a worry remains that, by taking meat as the norm,

fake meat capitulates to carnism. Defenders of fake meat argue that such products help people transition away from carnal meat. Perhaps in the future, if fake meat aids in persuading enough consumers to overcome carnism, vegans will be content with foods that look like fruits, vegetables, grains, legumes, nuts, and seeds.

[Agricultural systems](#); [Farmers' choices](#)

Introduction

Interest in agricultural systems has surged in recent years for the eating public. Bestsellers like *The Omnivore's Dilemma* and *Food Inc.* are household names, and most Americans have considered the meaning of food terms like “organic,” “conventional,” and “GMOs.”

Behind the neatly packaged terms is a complex web of management choices about such details as labor practices, soil fertility, and pest invasion. The set of choices available to a modern farm manager is heavily shaped by government policies and corporate influence, while the specific choices they make are based on his/her resources, skills, climate, land base, economic situation, and social context.

This entry endeavors to paint, with a very broad brush, a picture of the kinds of decisions farm managers face and the larger implications of those choices.

Decisions Faced by Farmers

Managers create systems to control the following primary factors that affect farm success.

Farm Labor: Who Will Do the Farm Work and How?

In the simplest subsistence farming scenario, the caloric yield of the food produced by farm laborers must at least be equal to the caloric output they and their nonworking family members use to live. Specialized economies require that the

productivity of farm laborers exceeds the needs of their families such that there is enough leftover yield to feed additional individuals who do not produce food.

A society in which there are some well-fed people who do not work on the farm requires that farm managers maximize the margin between the value put into each hour of farm labor and the corresponding yield per hour worked.

Chattel slavery on American plantations is one extreme example in which farm managers minimized the value spent on each hour of farm labor in order to maintain that margin between expenditures on labor and yield per hours worked. Today, many farm managers pay low wages and avoid legally mandated worker protections by employing undocumented workers with the same goal in mind.

These examples have clear ethical consequences that must be considered by farm managers, consumers, and policy makers alike. Cheap farm labor is one of two major factors that keep food prices low, allowing for the existence of well-fed members of society who do not engage in the work that feeds them (Mazoyer and Roudart 2006).

The second major factor in maintaining this distance between the value put into each hour of farm labor and the corresponding yield per hour worked is the maximization of yield, a factor that informs the decisions that face farm managers in the categories of soil fertility, pests, climate control, and what to grow as described below.

Fertility: How Will Crops Receive the Nutrients They Need to Grow?

Human beings cannot manufacture their own sustenance but rather must rely on the ability of plants to convert carbon dioxide and water into carbohydrates with the use of light energy.

The photosynthetic process is not only the basis of our diets, whether we eat plants or the meat of animals that eat plants. It also creates the biomass (organic matter) necessary to maintain a soil's capacity to produce food. When farmers harvest crops or graze livestock, they remove both biomass and minerals from the land in order to feed people. They must then make a choice of how to return biomass and minerals to

the soil in order to produce successive crops (Mazoyer and Roudart 2006).

While modern farmers tend to choose fertilizers based on available resources, climate, land type, and experience, those choices have larger implications for the food systems and ecosystems they are a part of. The range of strategies for fertilizing soils that is available in modern agriculture includes the following:

- *Manure and Compost* – The nutritional profile of a particular animal waste sample will reflect the food source of that animal. Most livestock manures used in agricultural production contain both macro and micro mineral nutrients as well as diverse organic molecules. Compost is fully decomposed manure or other biomass and is a very stable form of fertility that is easily tied up in soils (Coleman 1989).
- *Green Manure* – Planting green manures (also called cover crops) adds biomass to the soil and, in the case of legume plantings, can fix nitrogen from the atmosphere. Farmers plant cover crops in between cash crops either temporally or spatially (Coleman 1989).
- *Fallowing* – The “resting” of land between crop productions serves many of the same functions that cover crops do in that the regrowth of vegetation on fallowed land replenishes organic matter in the soil. Slash and burn techniques (Mazoyer and Roudart 2006) as well as Shmita fallowing (Deutscher and Hanau 2012) fall under this category.
- *Manufactured Fertilizers* – The Haber-Bosch process developed after World War II pulls nitrogen out of the atmosphere and concentrates it into shippable, spreadable pellets under high heat and pressure. Other mineral nutrients are processed from ores into soluble forms. These procedures are fossil fuel intensive and rely on industrial factories for their production (Mazoyer and Roudart 2006).
- *Rocks, Bones, and Shells* – Many essential plant minerals can be depleted from agricultural soils over time and may be sourced from elsewhere and reintroduced, either from powdered ores or animal processing by-products (Mazoyer and Roudart 2006).

Solubility of Fertilizers

When fertilizers are lost from a farm ecosystem through leaching, the long-term viability of farm soils is reduced and broad implications are triggered off the farm. Nitrogen and phosphorus pollution can cause eutrophication in surface waters making them inhospitable to many life forms. This is strikingly visible in many lakes in agricultural areas and at the mouth of the Mississippi River (Mazoyer and Roudart 2006).

Green manuring is the most complicated fertility system to manage, yet the organic matter it produces is readily tied up in the soil food web which increases the long-term productivity of soil and reduces the possibility for pollution. Ammonia fertilizers, on the other hand, are the most soluble and thus provide a quick food source for plants but no long-term fertility to soils while contributing significantly to nitrate pollution. Manure, if applied at the wrong time or excessively, can also run off as nitrate pollution but is more easily tied up in the soil food web than ammonia fertilizers (Coleman 1989).

Economics of Choosing a Fertilizer

There is also the factor of expense and economic relationships to consider. Manure is a by-product of livestock production that is free on farms that raise animals. Compost is also easily produced on farms from available materials. Both manuring and composting reappropriate materials that are already in existence for fertilizers. Green manuring requires the initial purchase or growing of cover crop seed. Manufactured fertilizers are by far the most expensive way to renew fertility on the farm and require the most reliance on annual purchase from the large corporations that produce them (Mazoyer and Roudart 2006).

Fossil Fuel and Carbon Emission Considerations in Fertilizer Choices

The production of manufactured ammonia fertilizer is by far the largest contributor to agricultural fossil fuel use. Transportation of fertilizers across long distances is also a contributor.

Competition: How to Favor Crops Over Other Species of Pests, Weeds, and Disease?

Farmers manipulate ecosystems to tip the competitive balance in favor of the plants and animals they hope to harvest. Pests, weeds, and disease are all organisms that attempt to grow in a farm ecosystem and must be minimized by farm managers using the following available strategies:

- *Biological Diversity* – The competition between organisms in an ecosystem can keep any individual pest or disease. Farmers try to increase biological diversity and specifically try to increase the number of predator species who feed on pests by:
 - Planting flowers or hedge rows to create habitat for beneficial insects like parasitic wasps or lady bugs
 - Releasing large numbers of predator species
 - Aerating soil and adding organic matter to create habitat for beneficial microbes
 - Applying foliar sprays that are rich in diverse microbes (Coleman 1989)
- *Climate Control* – Plants and animals are more likely to thrive in the face of competition when their needs for appropriate temperatures and water quantities are met. Farmers use irrigation and grow varieties that are well adapted to their climate to give crops an advantage (Coleman 1989).
- *Chemicals* – Insecticides, herbicides, and fungicides are all methods for coping with unwanted competition. While some chemicals target specific problematic organisms, others, called *broad spectrum* products, affect a wider range of organisms. These may be extracted from plants and microbes or designed from scratch in laboratories (Coleman 1989).
- *Mechanical Means* – Hand removal of pests, hand weeding, hoeing, tractor cultivation, and physical barriers are all examples of mechanical solutions to unwanted organisms (Coleman 1989).
- *Plant and Animal Breeding* – Throughout agricultural history, farmers have selected for varieties that resist local competition. The three common methods for breeding today are:
 - Classical Selection – The best plants from each generation are bred together leading to an improved population. Novel traits may be added from other populations or genetic mutation.
 - Hybridization – Unlike in classical selection, the breeder develops two crop lines and then breeds them to each other before use in normal crop production. This requires greater specialization in breeding and seed distribution infrastructure and generally does not allow for farmers to save their own seeds effectively.
 - Genetic Modification – While other breeding techniques are limited to closely related species, genetic modification allows genes from distantly related organisms, like plants and bacteria, to be combined in a crop variety. The process can be done in a number of ways, all of which must be done off the farm and are dependent on modern scientific expertise (Capon 1990).

Many of the above strategies conflict with the effectiveness of the others. For example, a farmer using broad spectrum insecticides will reduce biological diversity on his/her farm and may need to increase their use of chemicals each year. Similarly, a farmer who rids his/her fields of weeds through mechanical tillage may find that they continually introduce weed seeds from lower soil horizons while making a perfect seed bed for incoming weeds to germinate, requiring continued tillage.

Not only must farmers balance these potential conflicts when designing systems, they are often asked to consider other implications of their choices. Many chemicals are toxic to workers, compromising their health and requiring attention from the health-care system, and to wild species such as pollinators and birds that have wider implications for other farms and wild ecosystems. The use of fossil fuel powered machines contributes to greenhouse gases. Tillage releases carbon from soil while also freeing up nitrogen and phosphorus rich topsoil to flow into surface waters and cause pollution. Research on the ecosystem effects of GMOs interbreeding with other species is still incomplete.

Climate: How Can Water Availability and Weather Be Influenced to Favor Crops?

Farmers manipulate the water and microclimates on their farm as much as possible to create ideal conditions in which their plants and animals can thrive. Farmers irrigate from wells or water bodies such as rivers and ponds. They extend the length of their seasons using technologies such as greenhouses, barns, watering during late or early frosts, choosing hardy breeds, and mulching.

Crop or Animal Selection: What Should Be Raised on the Farm?

The landscapes of the world are shaped by the decisions farmers make around how to manage their land. The following factors may affect a farmer's decision of what to raise:

- Climate – As discussed above, farm success is largely dependent on how well adapted a crop or animal is to a particular climate. Farmers in the tropics are likely to raise a very different set of plants and animals than those in desert or cold temperate regions due to variation in temperature and rain fall. Certain crops and animals, like cows and corn, are more versatile than others and are thus present in a wider range of climates (Soloman 2005).
- Slope – Flat lands are much better suited to annual production of grains and vegetables than steep lands, which are better suited to grazing of perennial grasses or growing of perennial crops, due to risk of erosion (Soloman 2005).
- Soil Type – Soil texture (sand, silt, or clay), organic matter content, and nutrient profile are all factors that affect the decision of what to grow (Magdoff and Van Es 2009).
- Rotation Opportunities – The range of crops and animals raised on a given farm may be influenced by the ways in which the landscape and markets are conducive to crop rotation (Mohler and Johnson 2009).
- Available Resources – Capital, equipment, irrigation, fertilizers, labor, and seed are all examples of resources whose availability or lack of availability will affect a farmer's decision of what to raise (Byczynski 2006).
- Markets – If prices of a particular crop are high, farmers may be particularly motivated to grow that crop. Similarly, if the prices of inputs necessary for a particular crop are low, that may also affect a farmer's decision (Byczynski 2006). Agricultural prices are largely related to government policy, subsidies, international trade rules, commodity futures markets, demand set by the food manufacturing industry, and fossil fuel prices (NSAC 2008).
- Transportation – Fossil fuel prices and shipping availability impact whether a farmer will grow large quantities of a commodity or specialty crop that will not be used locally (NSAC 2008).
- Experience, Education, and Skills – A farmer can only choose a farming system that they have learned. Culture, government extension efforts, and nonprofit education initiatives all affect the sea of choices a farmer has to decide from.
- Pest, Disease, and Weed Pressure – Competitor species may limit the range of crops grown on a particular farm.
- Values – A farmer's ethical or religious beliefs may affect their decision of what to grow when deciding between plant or animal agriculture, diverse systems or monocultures, or fossil fuel-intensive systems or low input systems.

Off-Farm Dynamics That Affect Farm Decisions

Government Policies

The likelihood of a farmer to make any particular decision is affected by government policies in ways demonstrated by the following examples:

Access to cheap oil is maintained by government support via trade agreements, tax policy, and regulation. Systems that rely on manufactured fertilizers, long-distance food transport, diesel tractors, and heated greenhouses are only viable in a world where oil is inexpensive.

Commodity monocultures are a frequently chosen farm system in the USA, largely due to the subsidies offered by the federal government to corn, soy, and cotton farmers who grow wide acreage.

Public research and extension education has a vast impact on which farming systems are most developed and widely known to farmers.

In the USA, the Farm Bill largely shapes the management decisions farmers end up making. This large piece of legislation affects commodity prices through subsidies and government purchases for food aid, crop insurance availability, conservation incentives, farm credit availability, rural development, research, agroforestry, biofuel use, organic agriculture, meat processing, and access to land and education for beginning farmers (NSAC 2008).

Corporate Influence

Most American farmers receive a lot of information from large corporations like Monsanto, ConAgra, and Pioneer about farming systems that rely on the products those companies either sell (like fertilizers, GMO seeds, or chemical sprays) or want to buy (like cheap corn to make processed food).

Agribusiness affects farm management choices through its heavy lobbying efforts over the Farm Bill, patenting, control over research dollars, and marketing campaigns (NSAC 2008).

Culture

Farmers' choices are informed by cultural factors including generational wisdom passed down over time, expectations from community members, values and religious beliefs, and history of land use. There are vast difference between the farm management decisions made on an Amish farm, where tradition and low use of technology are highly emphasized, and those made on a large industrial monoculture farm, where high yields and expensive inputs are preferred.

Targeted Versus Systemic Approaches to Farm Decisions

Targeted Approach

Modern industrial agricultural systems tend to target individual biological problems with a great degree of effectiveness. Examples include the following:

- Chemical insecticide sprays that solve the problem of pest damage
- Monocultures that solve the problem of mechanical inefficiency in polycultures
- Antibiotics that solve the problem of livestock illness
- Tillage that solves the problem of opening up new ground for crop production
- Glyphosate resistance in GMO corn that solves the problem of weed management

In general, these targeted approaches allow for short-term high yields while creating new problems that compromise the potential longevity of the farming systems in which they are used and impacting the ecosystems and societies they are part of. This dynamic can be seen with the above examples in the following ways:

Chemical insecticide sprays may reduce biodiversity in the farm ecosystem eliminating the checks and balances that pest predators would otherwise provide and requiring an increase in spray schedule and quantities. They may also harm pollinators and wildlife that provide other ecosystem services in the area.

Monocultures tend to reduce biodiversity and thus require management from farmers that might otherwise be provided by ecosystem services in a polyculture.

Antibiotics can cause the microbes they target to evolve resistance, making their long-term use ineffective. They can also have negative effects on the humans that consume them or to wildlife who encounter them through ground water.

Tillage can cause widespread erosion such as in the case of the American dust bowl in the 1920s when deep-rooted grasses were tilled up, exposing fresh top soil to massively destructive winds and causing dust storms that devastated the region and lead to widespread lung disease.

Glyphosate resistance in GMO corn has allowed farmers to spray high dosages of glyphosate (an herbicide) and, in turn, enabled weeds to evolve resistance to the chemical.

Many of the long-term problems with targeted approaches to farm management stem from the

fact that they do not work with the nature of evolution which demonstrates that species succeed when they find a niche in which they are not outcompeted by other species *and* benefit from relationships with other species.

Systemic Approaches

Farm managers who choose a more systemic approach to decision making take into account the interplay of different species and parts of the food system. Examples of management choices that take a systemic approach include the cultivation of crop diversity, integration of plants and animals, reduced tillage, cultivation of wild habitat, cover cropping, and crop rotation (Coleman 1989). These approaches often result in lower annual yields as well, a need for higher labor input per caloric output, and reduced efficiencies compared to that achieved by larger-scale agriculture.

Gender Dynamics in Farm Management

Gender dynamics affect farm management decisions and the involvement of different farmers in those decisions in many ways. Below is a brief introduction to a few of the myriad ways in which this can happen.

Child Care Responsibilities – These have often traditionally fallen to women, limiting their ability to be physically present or fully engaged in farm decisions in some cases and/or shaping their opinions of how the farm should run in some cases. Pregnancy and breastfeeding can limit a woman's physical capacity for farm work for periods of time.

Training and Tools – American women often find it difficult to access training in traditionally male-dominated areas such as carpentry, mechanics, and heavy equipment operation. The tendency in American culture is for girls to have less exposure to tools than boys – sometime setting them up for a lifetime of low-confidence and lesser skills in those areas. Men are sometimes shut out of traditionally female aspects of farm life including family management and customer interface.

Gender Binaries in Farm Management – The cultural separation of women's work and men's work persists on many farms. In some cases, this

narrows farmer's capacity for nuanced gender expression.

Discrimination – Women long experienced discrimination in receiving farm credit through government programs (Zeuli and King 1998).

Summary

The primary factors that farm managers control to enhance the success of their farms are labor; fertility; competition from pests, weeds, and disease; climate; and end products. They do so through some combination of a targeted and systemic approach. Government policy, corporate influence, and culture are larger societal forces that affect the specific decisions made by farm managers. Child care, training, gender binaries, and discrimination are all aspects of the gender dynamics influencing farm management decisions.

Introduction

The Farm to School movement emerged in the United States in the mid-1990s with the goal of connecting schools and local farms to improve student nutrition and strengthen farming economies. The movement engages a number of organizations, businesses, agencies, and activists in

Farm to School has developed a wide variety of programs and initiatives to achieve these goals, such as establishing school gardens, taking student field trips to local farms and orchards, scheduling regular taste tests and inviting local farmers to provide cooking demonstrations in school cafeterias, and actively pursuing partnerships with local farms to increase sales of fresh, minimally processed produce to school kitchens. Attaining these outcomes often involves partnerships with local organizations which, in the past, typically did not work together, creating complex networks of producers, consumers, and distributors within local communities.

Developing and Sustaining the Movement

History and Key Actors

The Farm to School movement incorporates a holistic and synergistic perspective of health and well-being that places children within a web of other stakeholders, asserting that improving bodily health can be part of a system that strives to simultaneously create healthy farms, economies, schools, and environments. Historically, school nutrition programs have focused on providing meals that meet specific local, state, and federal dietary guidelines set to improve children's intake of vitamins and protein and limit their intake of fats and sugars. Federal initiatives such as MyPlate and the Food Pyramid were developed to increase children's awareness of nutrition intake of foods, serving and portion

sizes, and minimum number of servings of different food groups. Additionally, problems in world markets for commodities in the 1970s led to the amendment of the National School Lunch Act requiring schools to purchase commodity foods, foods like corn syrup and vegetable oils that are used in processed industrial food products (Poppendieck 2010). To stay within cash-strapped budgets, schools satisfy both dietary guidelines and commodity food requirements by designing menus and meal plans using the most inexpensive foods available, opting to buy canned, frozen, dried, and reconstituted food from large-scale distributors. The confluence of prescribed dietary guidelines and commodity food purchase requirements effectively precluded sales from small- and middle-scale farmers in their locales.

Farm to School movement advocates have sought to reverse this economy of scale, arguing that reliance on large-scale food distributors has been detrimental to children's health, local economies, and local farmers. The first Farm to School programs were developed in the mid- 1990s in California, Florida, and Connecticut (Feenstra and Ohmart 2012), primarily as a response to public health reports about escalating childhood obesity rates and growing concern about children's decreased consumption of fruits and vegetables (Center for Disease Control 2017). All of these initial programs were a result of partnerships between and among local universities, school districts, nonprofits (such as Alice Waters' Chez Panisse Foundation in Northern California), and local farms and/or farming cooperatives. Advocates of early Farm to School programs pointed to their successful increases in local farm purchases to area school districts and children's enthusiasm for projects such as the Edible Schoolyard at Berkeley's Martin Luther King, Jr. Middle School, a school garden maintained by students and used to supply the school's cafeteria needs (Poppendieck 2010). Momentum for the Farm to School movement burgeoned, and in 2002, the first Farm to cafeteria conference was held in Seattle. By the mid-2000s, what began with the concerted efforts of only a few states grew, encompassing programs in 40 states nationwide (Feenstra and Ohmart 2012). In 2007, the

National Farm to School Network was founded, a web of activists committed to changing the school food system from "farm to fork" (National Farm to School Network 2017). By the end of the first decade of the twenty-first century, many states had developed Farm to School initiatives as part of their school meal programs; for example, in 2009, Act 293 in Wisconsin established the statewide Farm to School program, housed within the Department of Agriculture, Trade and Consumer Protection (National Farm to School Network 2017).

In 2010, Michelle Obama's *Let's Move!* campaign provided a national and well-publicized platform to further consolidate efforts to promote small-scale gardening, family farms, and healthy eating, particularly for children (Obama White House Archives 2017). That same year, the Healthy, Hunger-Free Kids Act (P.L. 111–296) was passed, providing increased funding for school meals – a necessity for the expansion of sales of fresh, locally sourced fruits and vegetables as part of Farm to School programs (National Conference of State Legislatures 2011).

Moreover, the approved Farm Bill in 2012 included a provision allowing increased school district procurement of locally sourced, instead of commodity, foods (Feenstra and Ohmart 2012). All of this paved the way for the incorporation of Farm to School initiatives as part of the United States Department of Agriculture, specifically through its Know Your Farmer/Know Your Food program, and established the USDA's Farm to School Grant program to fund the creation, implementation, and assessment of Farm to School initiatives around the country (USDA 2017b). Furthermore, the leading national organization for Farm to School, the National Farm to School Network (a project funded by the Tides Center), developed Seed Change in 2014, a mini-grant program eligible to school districts attempting to establish Farm to School programming (National Farm to School Network 2017).

Program Administration

During the 2013–2014 academic year, the USDA conducted the most comprehensive, nationwide Farm to School census and found that 5254

districts with 42,587 schools are participating in Farm to School programming, from all 50 states, which is 42% of all districts surveyed (USDA 2017a). Survey results show a variety of programs and initiatives within the umbrella of Farm to School. The top five most common Farm to School activities, by percentage of surveyed schools who indicated engagement in that activity, are:

1. Serving locally produced foods in cafeteria (77%)
2. Promoting locally produced foods at school (37%)
3. Holding taste tests/demonstrations of locally produced foods (33%)
4. Conducting student field trips to farms/orchards (31%)
5. Other in-cafeteria strategies and activities to encourage consumption of local foods (31%)

The survey results indicate that Farm to School activities have a presence at every level of the educational system, taking place in 83% of elementary schools (Grades K–5), 66% of middle schools (Grades 6–8), and 58% of high schools (Grades 9–12). Most of the activities are associated with lunches (86%), while 54% of activities involve breakfasts, 20% involve snacks, and 6% involve school supper programs. Census results suggest that “local foods” are defined entirely by school districts and determined within specific parameters, such as foods procured within the state, within specific counties, or within a particular mile radius.

In La Crosse, Wisconsin, for example, local Farm to School activities (abbreviated to F2S or Farm2School) include establishing school gardens at select elementary schools; serving as many locally sourced fruits and vegetables as possible in school meals; establishing school salad bars with locally sourced foods; scheduling “Taste Test Tuesdays” with “Harvest of the Month” foods, in which children can taste test menu items made with locally sourced foods, such as rutabaga soup, kale chips, and raw kohlrabi coins; organizing cooking demonstrations in school cafeterias, whereby children interact with

local farmers who provide Taste Test and Harvest of the Month foods; and hiring a “forager,” a public health official whose tasks are to mediate local farm food procurement in the school district and to assist school meal personnel in their preparation of fresh, minimally processed foods (Hippert et al. 2014; Get Active La Crosse 2017). Farm2School in the La Crosse County School District partners not only with the La Crosse County Public Health Department and area farmers but also with AmeriCorps volunteers and organizations such as GROW La Crosse who are vital to the county forager with assisting and training school meal service personnel to adequately store, prepare, and cook with fresh, local foods that attract and appeal to children in the district.

Program Assessment

Evaluations of Farm to School programs have pointed out its benefits, challenges, and limitations. Program evaluations have been conducted within regions (e.g., the Midwest or Northeast), individual states, local school districts, or multiple school districts. For advocates of Farm to School, evaluations need to account for the interconnections between children, communities, schools, and farmers. Evaluations not only define and determine success using outcomes such as increasing children’s consumption of fruits and vegetables, or eating a wider variety of fruits and vegetables, but also for increased sales to local farms, creating and sustaining school gardens, increased school activities involving children in meal planning and cooking, and growing community and student awareness and activities related to food and environmental sustainability.

Increased school district participation in farm and school and changing children’s behaviors in school cafeterias have been key determinants in assessing programmatic success of Farm to School and its effects on children. For example, in a survey of food service directors participating in the state of Michigan’s Farm to School program, Colasanti et al. (2012) found that the number of schools and students participating in Farm to School had grown substantially throughout the state over a 5-year period. In 2004, school

participation rate in Farm to School rose from approximately 10% to almost 43% of Michigan schools, and 77% of all schools surveyed “had taken at least 1 step to connect children to local food.” Benson’s (2013) research showed that more than any other Farm to School activity, school gardens are the focal point for engaging student family members in Farm to School programs. In the state of Wisconsin, Botranger et al. (2014) found that among elementary school children participating in Farm to School programs, there was increased willingness to try Farm to School foods, increased consumption of fruits and vegetables among those children who had had the lowest intake of these foods prior to participating in Farm to School, and more observations of local foods on school lunch trays.

Evaluations of Farm to School also examine programmatic effects on school food service personnel. Because by definition Farm to School engages formerly disconnected stakeholders, one of the primary concerns of both farmers and food service personnel is increased efforts needed to source locally produced foods to satisfy meal planning. Responses from a survey of seven Farm to School programs in the Northeast and Midwest (Izumi et al. 2010) found important benefits of Farm to School: locally sourced food prices were comparable to large-scale distributors’ prices, and most participating food service directors expressed satisfaction with the variety of foods that Farm to School introduced children to in their meal planning. But like food service directors from other states, they were concerned about the increased time and effort needed to find locally sourced foods. In the state of Michigan, food service directors overwhelmingly expressed a deep desire to participate in Farm to School because of its links to the local farming economy (Colasanti et al. 2012). However, the same evaluation revealed that food service directors are also concerned about the higher cost of Farm to School foods and logistical problems with Farm to School procurement, such as not being able to engage in “one-stop shopping” (e.g., having to purchase produce from a different supplier than, say, meats and dairy products), which increased the amount of time and effort it took to procure needed supplies.

Evaluations of Farm to School often reveal food service personnel’s ambiguity with fulfilling their tasks in school kitchens with locally sourced foods. Farm to School programs require training food service personnel to cook with unfamiliar foods or create meal plans using fresh foods, foods that need more time and effort to prepare. In his comparison of various state-level Farm to School programs, Benson (2013) showed the importance of the role that state-level cooperative extension programs played in supporting and retraining food service personnel. In La Crosse, Wisconsin, the district-wide forager and local volunteers were necessary to assist school food service personnel with preparing fresh Farm to School foods, such as shucking hundreds of ears of fresh corn or cooking vegetables children are often unaccustomed to, such as rutabagas, asparagus, and turnips (Hippert et al. 2014).

Farm to School evaluations also uncover limitations and benefits to participating farmers. Izumi et al. (2010) found that while farmers’ primary motivation for participating in Farm to School is unlocking a formerly inaccessible market, most farmers also indicate that they accrue important social benefits from participation in the program. Farmers emphasized the responsibility they feel to contribute to the health of their communities and expressed a deep commitment to fostering children’s connections to healthy foods and environments. At times, Farm to School evaluations conclude that benefits to some stakeholders might be detrimental to other stakeholders. For example, Azuma and Fischer’s (2001) analysis of Farm to School programs in eight states found that the cooperation between local farms and schools necessary to build successful programs frequently is out of step with the fierce competition farmers face as they seek to access school markets. In Wisconsin, Hippert et al. (2014) found that, although a forager helped facilitate the school district’s procurement of foods through local farms, thereby reducing the time and effort food service directors spent sourcing local foods, farmers were concerned about competition between and among themselves for entrée into the local school market.

Farm to School evaluations also reveal challenges faced by school districts located in temperate climates, particularly those with harsh winters and short growing seasons. In these districts, the academic year is out of synch with the seasonality of a large variety of locally grown fruits and vegetables, severely limiting meal planning and food procurement. Benson (2013), Azuma and Fischer (2001), and Feenstra and Ohmart (2012) discuss the importance of training school meal personnel and refurbishing school kitchens to fulfill the need to preserve local foods for later use. Structural changes, such as refurbishing school kitchens, require large economic investments, a barrier for most school districts. The limitations created by short growing seasons and harsh winters mean that Farm to School food procurement is feasible only during the fall and spring of the school year. If local farmers use hoop houses or greenhouses to overwinter some crops, then food procurement for certain vegetables, such as leafy greens, may be possible during winter months. Eliminating the interruption of Farm to School food procurement during the school year benefits farmers, whose sales increase; food service directors, who have a smoother transition in month-to-month ordering of supplies; and children, who come to rely on the tastes, textures, smells, and appearance of recipes that include local foods.

Because of the relatively recent development of and participation in Farm to School programs, longer-term impacts of Farm to School have remained elusive. For example, there has been scant research on Farm to School that discusses its effects on childhood overweight and obesity rates, which was one of the primary rationales that initiated the Farm to School movement. In most school districts where Farm to School foods are only consumed for one or perhaps two meals a day, there are too many confounding variables to suggest that Farm to School programs alone make a difference in children's weight. Moreover, there is little information to date on the effects of Farm to School programming on students' families, the integration of students' families in Farm to School programming, or the level of influence Farm to School has in modifying students' diets at home. Finally, there is growing concern about the

economic sustainability and viability of Farm to School programming, particularly because start-up costs for Farm to School are generated initially through grants (Feenstra and Ohmart 2012). Whether Farm to School program costs are absorbed in school districts' budgets remains to be seen.

Conclusion

The Farm to School movement in the United States emerged as a response to concerns about childhood health problems, such as increasing overweight and obesity rates, and the disconnect between people and the food they eat. Unlike other nutrition programs, Farm to School creates a web of social relationships to promote children's health along with the health of local farms, economies, and the environment. Farm to School uses a variety of different programs, such as establishing school gardens, increasing locally sourced food purchases in schools, modifying school menus to include a wider variety of locally sourced foods, and expanding community awareness of who is growing our food and where/how it is grown. Since the early 2000s, school participation rates in Farm to School have soared, and Farm to School activities have become a part of national health initiatives and school nutrition policies. Evaluations of Farm to School show high motivation for involving children in Farm to School activities. However, school districts face a number of challenges in sustaining Farm to School for the long term due to a number of factors: the problem of the seasonality of foods when school is in session; unfamiliarity with a variety of foods; uncertainty of food preparation to appeal to children's expectations; the time, effort, and cost necessary to buy from dispersed local farms; and the overreliance of funds from grants to support Farm to School activities. Farm to School, as a movement, contributes to the creation of an alternative, locally based food system and incorporates stakeholders who typically have been excluded from the industrial food system set up to accommodate schools. To meet common goals, Farm to School programs have developed

a number of strategies and activities, the variety of which prohibits a one-size-fits-all system of evaluation. Yet instead of focusing on the product, the ultimate success of Farm to School may be found in the process itself: connecting children, farmers, community activists, and schools and striving toward maintaining the health of everyone involved.

Introduction

Building on the diversity of agricultural practices and the observation that even under similar conditions, not all farmers make similar choices,

farmer types are often used to distinguish between groups (or types) of farmers. A farmer type is usually described through the interrelationships between attributes, e.g., farmers' socioeconomic characteristics, their values, the characteristics of their enterprises, and their biophysical assets. Farmer types are thus a means to make sense of the complex relationships between multiple factors that can influence farmer behavior.

This entry illustrates how typologies have been used in a range of studies, e.g., on how farmer types differ in their motivation to adopt technologies or to implement a voluntary policy measure. But first the notion of typologies is presented and some limitations pointed out.

Of Typologies. . .

Typologies are well-established analytic tools in the social sciences. They are used to form concepts, to explore dimensions of these concepts, or to organize explanatory claims. While they can be used to describe diversity, the aim of building typologies is usually to explain a phenomenon, e.g., nonadoption of a technology that seemed promising. They are also used to customize recommendations, e.g., how a policy measure should be designed to increase the likelihood that it will be adopted by the target farmer group.

Every typology is the result of a **grouping process**: a population of farmers is divided into types which are distinct from each other regarding the issue under consideration. The main requirement is to form types so that the farmers within a type are as similar as possible and the differences between the types are as strong as possible. A farmer type is thus a constructed subgroup that is described by a particular combination of the value or expression of the attributes. The attributes used to group farmers are usually based on the researcher's theoretical understanding of the issue of interest (Kluge 2000). These attributes should be linked not only by empirical correlation but by meaningful relationships. The farmer type is then described by the "typical" combination of attributes, e.g., practices and attitudes. Usually, each farmer type is labeled using terms that

evoke relevant concepts, e.g., “productivist” and “lifestyler.”

A farmer typology is often based on survey **data** which may include quantitative, ordinal, or nominal data, e.g., farm size and farmer characteristics such as gender, age, education, and attitudes. This approach allows the identification of farmer types using statistical methods, such as multivariate analysis and clustering (e.g., Mann and Gairing 2012). However, farmer types may also be built using qualitative data, e.g., from interviews focusing on the farmer’s perception and declared strategy (e.g., Fairweather and Keating 1994). Whereas many typologies are constructed by the researcher, there are also participatory approaches to identifying farmer types, often in the form of an iterative process where potential types are built using the multivariate analysis and then refined in discussion with farmers or extension agents (e.g. Girard 2006). In the latter approach, the goal is not only to capture farm diversity but also to enhance mutual understanding and stimulate collective learning.

...And Their Limitations

Typologies can be useful to establish informative connections between attributes and highlighting how the values of the attributes are similar or different between types. As such they allow identifying differences and pointing out conceptual structures. However, some words of caution are in order. First, as usual, care needs to be taken to clarify to what extent the **correlations** on which a typology is built are linked to causation of the outcome. In other words, to achieve a suitable interpretation, it must be ascertained that the empirical regularities build on meaningful relationships.

Also, identifying and describing a “handful” of farmer types (typically three to five) tend to emphasize differences between types and to imply homogeneity within a type. However, while differentiating between farmer types has clear **heuristic value**, in practice each farmer is in a unique situation. As such it is likely that a number of farmers will display characteristics of

several types, making it a challenge to assign him/her to one type. Empirically the problem is solved by either assigning an individual case to the farmer type of which he/she displays most characteristics or creating a separate farmer type for all those cases that cannot unequivocally be classified to any of the farmer types. However, once the empirical problem has been solved and the types look neat, it is easy to downplay the fitting process and highlight the differences between the types. Two forms of reification can thus be distinguished: on the one hand, it should not be (implicitly or explicitly) suggested that the types defined in the study describe types of farmers as they exist in the world. On the other hand, the label assigned to each farmer type should not become a free-standing “explanation,” leading to simplification and stereotyping. In other words, it is important to keep in mind that while typologies are useful as epistemological devices – i.e., as a means of engaging with a situation so as to better inquire it – they should not be given ontological status.

Finally, typologies are necessarily a snapshot at a **one point in time**, capturing a specific configuration of options, perceptions, and relationships. However, farm strategies and farmer motivations are not static. They are dependent on farmer preferences, which change, e.g., in the course of the life cycle, and on how farmers perceive the opportunities and constraints of the context in which they act. Given that this context is constantly evolving, it is unclear to what extent a typology will hold over time, i.e., whether the identified attributes remain the most salient ones. Indeed, based on a systemic understanding of farming, every change (e.g., in prices, networks, regulations, family labor availability) will change the configuration of the system and thus the “option space” and may well have an impact on how an opportunity is perceived or on the motivation to adopt a specific practice.

Farmer Types and Motivation

Research on farmer types was initiated as a result of the observation that new technologies or

practices were not evenly adopted, and the heterogeneity could not satisfactorily be explained by farm structure (e.g., farm size, farm ownership, labor availability, agroecosystem). This challenged the concepts of economically rational choice and technological determinism, thus highlighting **farmer agency**. It increasingly became clear that farmers' perception of a technology and the degree to which it fit with his/her personal farming aspirations play an important role on whether and how it is adopted. Indeed, even once adopted, a technology is not uniformly implemented, as farmers use it to different ends depending on their individual understanding and preferences (Glenna et al. 2011).

Attention was given to farmer perceptions and farming goals as possible influencing factors, as well as to understanding various reasons for and perceived constraints against adoption. Researchers thus increasingly took into consideration **motivation**, i.e., attempted to understand how different cognitive frames inform and shape attitudes. The aim was to provide insights into why, when two farmers in seemingly identical situations are confronted with the same opportunity, one farmer elects to pursue it and the other does not.

The interest in farmer types and motivation was initially linked to research on **adoption of new technologies** such as improved seeds, agri-chemicals, machinery, or irrigation. Indeed, in the 1960s and 1970s, the notion of progress built on farmers adopting the technologies developed by researchers; thus, high adoption rates were the prime indicator of progress and success. Since the 1980s research on farmer types is often linked to understanding which type of farmer does (not) adopt environmentally friendly practices, e.g., cover crops to prevent soil erosion or careful management of water in irrigation schemes (Emtage et al. 2006). This topic of research rose in prominence with the advent of policies seeking to induce farmers to implement practices that are publicly desirable, esp. in the context of environmental protection. For example, in the European Union, voluntary **agri-environmental measures** are a key policy instrument within the Common Agricultural Policy. But such policy measures have no impact per se: they are mediated through

farmers' perceptions and practices. Thus, understanding farmers' motivations for participation in these voluntary schemes is crucial to understand their effectiveness (Morris and Potter 1995; Riley 2011).

In the context of technology adoption, research was often based on **theories of innovation**. For example, the diffusion of innovation emphasizes the role of information, risk, and the social position of the farmers, distinguishing between "early adopters" and "laggards." Generally, this approach highlights the role of farmers and their predisposition to accept change and to innovate (Morris et al. 2000). A number of studies on technology adoption focus on the perception of **risk and uncertainty** linked with the new technology. Indeed, even if the general properties of a technology are known, the consequences and outcomes for a specific farm can never be certain. As such the perception of riskiness of a technology, attitudes to risk, and the role of trialing and learning have been shown to play a role in the adoption of a technology (Greiner et al. 2009).

In the context of modernization, i.e., the overall process of intensification, specialization, and mechanization, attention has been given to the process of structural change and strategy adjustment. Here the debate tends to center on the extent to which farmer motivation and strategy can be linked to an approach termed "**productivism**" (Walford 2003; Soini et al. 2012). Farmers following a "productivist" strategy tend to be committed to an intensive, industrially driven, and expansionist agriculture. On the other hand, "post-productivist" (or "multifunctional") farmers are oriented towards extensification and diversification, targeting some of their activities towards the production of public goods, e.g., in the framework of area-based payments. While the discourse regarding productivism versus post-productivism often focuses on structures and practices, these are also understood as an expression of the values and motivations which underlie behavior.

Focusing on the fundamental aspirations linked to farming, which is one of the key determinants for farmers' strategies, a number of studies have focused on farmer types based on the relative importance of farming for **family income**.

In this context, farmer types range from those who manage agricultural land as a recreational activity (i.e., “hobby” and “lifestyle” farmers), those who mainly aim to produce food for their family (subsistence farmers), and those for whom farming is a source of income (i.e., part- and full-time farmers). These types are linked to differences in values and objectives, e.g., the relative importance of economic, environmental conservation, and community values. For example, a study by Kuehne et al. (2007) distinguishes between three farmer types: the “lifestyler” who has a strong relationship with the local community and to the land, and may not expect an income from farming; the “custodian” who focuses on the continuation of a (reasonably profitable) family business and wants to work with family members; and the “investor” who emphasizes economic considerations when making farming decisions. Thus, as in most typologies, economic, environmental, and community values are not mutually exclusive, but rather emphasized to varying degrees.

An approach to avoid reducing farming strategy to economic and technical rationality is to focus on how farmers mediate external pressures and construct a room for maneuver. The “**styles of farming**” approach (van der Ploeg 1993) highlights different farmer types, depending on the extent to which they choose to rely on markets for inputs and to selectively enroll technologies. This approach distinguishes several farmer types by identifying the logic underlying their practices. For example, the “economical farmers” strive to minimize monetary costs, rely on their skill, and maximize labor productivity, whereas “intensive farmers” specialize, mobilize resources through markets, and rely on mechanization. Importantly, the styles of farming are emic types and thus refer to a cultural repertoire and to normative ideas how farming “should” be done. They are also understood as expressions of farmers struggling to realize their own projects and resist external pressures. Indeed, markets and technology are seldom perceived in a neutral manner by farmers, especially since policy and agribusiness endeavor to bend the relations involved to their own particular development projects.

Another application of farmer typologies is explaining the multiple goals of the varying

management styles, not least because this approach may help to understand their strategic orientation. For example, Fairweather and Keating (1994) describe three types of farmers: firstly, the “dedicated producer” who thrives on farm work, whose goal is to achieve a quality product, who emphasizes planning and financial management and has the goal of being the best farmer possible. Secondly, the “flexible strategist” who sees marketing as a key element in the success of the farm and who looks beyond the farm gate for both effective marketing and pursuing off-farm activities. Thirdly, the “environmentalist” who is most concerned by the environmental impacts farming may have and values working with family members. The management styles highlight how farmers combine both business and way of life goals in complex and personal ways. They also highlight the diversity of resources that can be mobilized and that can contribute to the resilience of farms in turbulent times.

Regarding the environmental values of farmers, a number of studies have tried to assess its role, especially in the context of the adoption of voluntarily policy measures: do farmers enter a contractual agreement because they seek to increase their income or because it is in accordance with their environmental values? In this context conversion to **organic farming** has been a popular study topic, not least because it is one of the more demanding approaches to environmentally friendly farming. Such studies tend to distinguish between farmers who are “loyal” and “optimizers” (Mann and Gairing 2012) or between “committed” and “pragmatic” farmer types (e.g., Darnhofer et al. 2005). For “committed” or “loyal” farmers, conversion to organic farming was mostly driven by environmental values or health reasons, and they are seen as committed to the principles of organic farming and animal welfare. For “pragmatic” farmers, conversion to organic farming allowed them to implement their goal, e.g., an increased autonomy, the search for a professional challenge, or an increase in their farm income. This goal was enabled by the direct payments or higher prices

for organic food, so that economic rationality played an important role in the conversion, rather than adherence to organic principles.

More generally, studies have assessed farmers' perceptions of their environmental rights and responsibilities, not least given that the public debate increasingly prioritizes amenity provision and the recreation value of rural landscapes. One such study (Davies and Hodge 2007) identifies five notions of agricultural **stewardship**: the "environmentalists," "Jeffersonians," "yeomen," "commodity conservationists," and "progressives." The stewardship position of these farmer types ranges from ecocentric, i.e., a respect for nature that is opposed to an exclusively utilitarian approach to the use of living things, to a concern to maintain an aesthetically appealing countryside and to a robust support for modern farming methods and a rejection of the premise that agriculture is causing environmental damage. Such studies can inform policy makers concerned with the effectiveness of policy measures. Indeed, if the design and communication of regulations take into account how they will be perceived by the target groups, it can increase their acceptance and the legitimacy of controls, thus reducing the monitoring and enforcement costs.

While many studies take a static approach that sees motivations and practices as present-centered issues, other studies attempt to capture the **dynamic nature** of motivations affecting farmer's choices (Farmer-Bowers and Lane 2009). Indeed, adoption of a technology or of a policy measure is most likely the culmination of various interrelated factors and motivations, all of which change over time. This temporal dimension is of particular importance in family farms, where farm continuity and succession play a key role, and thus a long-term perspective is integrated in strategic decisions, shaping farm development pathways. The question then is: how can technologies or policy measures be incorporated into dynamic farm development pathways to enable this continuity (Ingram et al. 2013). Farmers' motivations for ensuring the continuity of the farm are wrapped up with those for ensuring the continuity of their farming values. Thus, adoption

or participation decisions are taken in the context of comparing other possible future options and at the same time referencing them to the past, both with respect to what is perceived as possible and as acceptable. Farmer types thus benefit from taking into account that farm strategies emerge in response to a continuously changing context as farmers actively create and exploit opportunities in their desire to sustain and shape the future of the family farm.

Summary

Farmer types aim at explaining differential responses to similar structural circumstances. Research shows both the influence of extrinsic and intrinsic motivations, e.g., financial rewards, and the satisfaction of personal values, goals, and self-fulfillment. They have also shown the influence of cultural norms, identity, social, and cultural context. As such farmer types highlight the **interplay and mutual influence of internal and external factors** and relationships, recognizing the central role played by farmer agency. Yet, while typologies are a useful way to structure the empirical heterogeneity, it is important to keep in mind that there is a wide diversity within each farmer type. Also, the label chosen for a farmer type tends to highlight one characteristic of the type, which might be getting more prominence than it deserves and might convey a one-dimensional concept, masking both the complexity and the dynamic of farmers' motives.

Research on farmer types is usually situated within the **actor-oriented paradigm**: farmers are not simply seen as passive recipients of intervention, but as active participants who process information and strategize. Thus, typologies build on the assumption that the differential farming patterns that arise are in part the creation of the farmers themselves. Yet, there is a tendency to build farmer types in terms of individual motivations, intentions, and interests. While this might be an improvement compared to studies that build on structural determinism and rational economic choice, the voluntaristic view of decision making tends to give insufficient attention to examining

how individual choices are shaped by larger frames of meaning and action, by the distribution of power and resources in the wider context.

Farmers' Markets

Synonyms

Direct marketing; Growers' market; Producers' market

Introduction

It has been observed recently that there is a growing social appetite for the “story” that surrounds food products and the modern food system. Part of this unfolding and evolving story involves a resurgence of interest in foods and farm commodities of local and regional provenance (Feagan 2007). The reasons for this are rehearsed elsewhere in this volume in relation to local food and in an expansive and expanding literature on Alternative Agri-Food Networks. However, it is in this context that there is renewed interest in one long-standing feature of the North American food retail landscape, in particular, the **farmers' market**. While there is much variation in the scale, structure, and organizational details among and between specific iterations of this form of food marketing, a farmers' market is generally understood to be a regularly recurring market at a fixed geographical location (with or without associated infrastructure) where farmer/producers and consumers engage in direct exchange for agricultural products. The degree to which specific markets hold to this simple formula is a matter of considerable interest and at times consternation, and elements of this tension will be highlighted subsequently.

Though farmers' markets have a long history in North America, mainstream interest in them generally spans on a period of expansion, decline, and revival through the mid-twentieth century and into the current era. In its early incarnations in this

period, the role of the farmers' market was basic and seemingly straightforward – to provide a regular venue for local farmers and consumers to congregate and engage in the sale and procurement of food staples. In this sense they were “everyday” places where food producers sold the fruit of their labors to householders in their communities and regions. However, farmers' markets faced a decline following WWII due to the increasing mobility of people, the proliferation of processing and refrigeration technologies, the advent of supermarket chains, and the shifting public sensibilities concerning what constituted “good” food. Over time, the role of farmers' markets in the food landscape became less certain, and many of them were relegated to the economic margins or disappeared completely. Readers wishing more specific details of the rise, fall, and reinvigoration of farmers' markets in America should consult an excellent review by Brown (2002) that traces this evolution.

Over recent decades farmers' markets have been resurgent across North America and have emerged and grown rapidly as a *new* innovation in countries such as Australia and New Zealand. In other “old world” regions too, farmers' markets remain alive and well but now much invigorated through strategic alliances with local and slow food movements and a variety of state-sponsored rural regional development initiatives. The so-called *new generation* farmers' market is an exciting, and at times contested, arena in which values, beliefs, preferences, and aspirations around farming and food are finding expression market day by market day (Holloway and Kneafsey 2000). In practical terms they serve as an intuitively obvious site for food producers and consumers to find each other – physical spaces in which immediacy and directness can be (re)introduced into transactions around food. For producers, this presents the possibility of capturing greater value from the food product being sold; for consumers, the chance to obtain products with (allegedly) enhanced qualities; and for organizational actors, the chance to operationalize trade in local and quality food on terms that they can dictate and attempt to regulate. A more analytical

view sees them not just as a site of economic transactions but also as a venue for negotiated meaning, value, and, perhaps, common purpose in the local food landscape – a space for the expression and development of community. In light of this complexity and nuance, the approach taken in this entry is to rehearse some of the most frequently arising themes, claims, and tensions in relation to contemporary farmers' markets with attention paid to four elements: producer benefits, consumer expectations and experiences, contested authenticity, and community building.

The Farmers' Market as an Economic Space: Producer Motives and Benefits

At or near the top of the list of alleged benefits and opportunities associated with the contemporary farmers' market is the assertion that they represent for some farmers an alternative to the corporatized, vertically integrated, and highly consolidated conventional food supply chain and its associated marketing structures. Indeed, a large body of literature has traced the causes and motivations for producers' migration to alternative commodities, enterprises, and markets. Not surprisingly, these derive strongly from the ongoing structural changes associated with the industrialization of farming and include producer recognition of the environmental consequences of intensive agriculture, poor profitability in the conventional farm sector, loss of autonomy and control over production and marketing practices (either because of formal or de facto subsumption by agrobusiness), and a strong sense of a deteriorating quality of life as the stresses associated with intensive agriculture find their way inside the farm family. As a consequence of these and other causal factors, growing numbers of farmers in North America and elsewhere have sought out opportunities for change with the intent of at least partially, if not completely, decoupling from the industrial model.

Research on the producer side of the farmers' market scene has found that growers are frequently motivated by perceived economic

opportunities (more sales, better prices, etc.) and a greater sense of control in their initial decision to attend, but eventually acknowledge the importance of collaboration and (healthy) competition with fellow vendors. Brown (2002) surveyed the literature on FMs in the United States spanning a 60-year period and summarized certain empirical regularities concerning both farmer/vendors and consumers. Those findings revealed that, in many instances, farmers participating in FMs were more likely to be operating on a comparatively small scale and reporting benefits in terms of reduced transport costs, the ability to deliver food quality and to lay claim to more benign environmental practices. The economic benefits of the markets to farmers themselves relate to comparatively low barriers to entry for farmers, the ability to capture and retain a greater portion of the selling price of goods, and, of course, the market's creation of a fixed (and in some instances fitted out) space for trading that provides easy access to food purchasers.

Beyond producer-direct benefits, a number of studies, particularly in North America, have examined the wider economic impact of farmers' markets in terms of job creation, aggregate agricultural sales, and related multiplier effects in regional economies. While the figures between regions and studies vary widely, the results do indeed show impressive impacts both within and beyond the farm sector in the form of job creation and associated earnings, total farm receipts, and new business start-ups (see, e.g., Brown and Miller 2008). Impacts annually in some US states such as Iowa are reported to exceed 20 million dollars. Though no one has yet suggested that the days of the supermarket and the vertically integrated commodity sectors are numbered, the economic impact of farmers' markets is real and rising steadily.

Among these wider economic benefits, much recent discussion of the future potential of farmers' markets concerns their ability to act as incubators for new farm and food ventures (Guthrie et al. 2006). Some or all of the following may provide impetus for this effect. First, there are increasing uncertainties and concerns in some quarters for the emergence of the next generation

of farmers in North America. In Canada, for example, based on recent national census data, the average age of farmers has risen steadily over recent decades and sat at 54 years of age in 2006. This, together with the fact that recent studies indicate that the majority of farmers today have no clearly developed plans for farm succession, raises questions about the face(s) of farming in the not too distant future. Given the well-documented exodus of youth from rural regions and the long-standing economic struggles of the traditional family farm, historical patterns of predominantly within-family farm succession may be no longer hold. The question then arises, “might farmers’ markets and other local food marketing initiatives become a catalyst for a new vision of farming and the food system that supports the entry of new farmers and the (re)emergence of smaller more locally focused farm enterprises?” Second, it is now well recognized that the conventional food system, and indeed many farmers’ markets, does not reflect in their food offerings, the expanding ethno-cultural diversity of their community and region. Across North America and presumably elsewhere, there is increasing recognition of the market opportunity presented by ethno-cultural consumers and the new farms and farmers they might support. Farmers’ markets are seen as a natural outlet, both economically and socially, for these new types of foods and farmers. Third, many smaller producers, particularly in the live-stock sector, currently lament the absence of processing and packaging infrastructure as much of this capacity is taken up by actors in the industrial food system – either through direct ownership or dominance through volume. It has been speculated that the rise of popularity in farmers’ markets, and their associated implications for the viability of small- and medium-scale farms, may also trigger the development of new local food system infrastructure in support of a sustainable alternative farm and food sector (Gillespie et al. 2007; Hinrichs et al. 2004). Given these possibilities, it is not surprising that the farmers’ market is now seen as a potential catalyst for positive change on the supply side of the local food equation.

Consumer Expectations (Big and Small): Marketing Quality and Experience

It has been suggested that the growing popularity of local food and venues such as the farmers’ market reflect the outcome of both a critical public assessment of the conventional food supply chain and an expanding consciousness of the potential to connect food choices and social values. Some academic literature has invoked the term “the concerned consumer” in reference to what is frequently believed about local food supporters. The assertion is that for at least some shoppers, the farmers’ market is an opportunity and a space in which they can pursue (either explicitly or implicitly) high-level goals such as sustainability, equity, social justice, and community. In this sense local food venues such as farmers’ markets can be seen as spaces of expression and opposition in a new and emerging *politics* of food. The degree to which this is accurate or evident at specific markets and among shoppers is amenable to friendly debate, but what can safely be said is that an important and recurrent part of the farmers’ market narrative (i.e., its story) is that it is different and distinct from the food retailing mainstream – a mainstream that has been accused of being often nonaligned with the social values noted above. Aside from these somewhat philosophical matters, there are a wide variety of other known and well-documented reasons why increasing numbers of people are being drawn to the farmers’ markets. In North America these include the so-called push factors such as the recurrence of well-documented food scares (with associated human health implications), the rejection of genetically modified foods by some food consumers, concerns over the environmental and ethical implications of intensive agriculture, and the decline of the family farm. Included among the most often noted pull factors are the revival of interest in fresh and freshly prepared food over processed commodities, the prospect of personal connection and a sense of belonging, and the lure of conviviality. Taken together, the bases for farmers’ market patronage span a wide array of material and symbolic demands and

values – many of which hold closely to the alleged tenets of local food systems.

Notwithstanding the high-level concerns and interests above, on any given market day, shoppers will express a far more pragmatic set of expectations, beliefs, and desired benefits regarding farmers' markets in general and their own market in particular. Studies indicate that perceptions of superior quality, freshness, and flavor are paramount with diversity and distinctiveness of product, price competitiveness, and the generally strong presence of organics as additional strong motivating factors (Smithers et al. 2008; Wolf et al. 2005). Beyond the sensory elements of food, consumer surveys at farmers' markets also confirm the importance of consumer confidence with respect to such matters as food safety and traceability and the methods of production. The presence of producers creates opportunity for information exchange on these important questions and creates also the possibility of sharing more general knowledge about food products and the nature of farming. A final, alleged consumer expectation is that they use the opportunity of conversation and clear signage to confirm the geographical provenance of the foods they purchase. While it is clearly believed, and the literature supports, that local *matters*, it has emerged in some studies that the geographical size of *local* varies according to region, season, and commodity and that, on the basis of other trust factors, shoppers may exhibit considerable flexibility in their demands so long as the spirit of local food is observed. Such flexibility can clearly be seen in the regulations and rules of engagement across jurisdictions and makes for spirited debate and at times tension at specific markets (see comments on Authenticity below)!

Before leaving the topic of consumer wants and expectations, it is important to note briefly one final and increasingly noticeable commodity at the market. In both scholarly writing and at the organizational level in farmers' market organizations, it is well recognized that one of the things being most actively consumed at many farmers' markets is the market experience itself. In this sense it has been suggested that at least some farmers' markets have become

commodified – something to be experienced and consumed quite apart from any considerations pertaining to the specifics of farmers and food or the lofty social goals noted earlier (see Miele 2006). This phenomenon is by no means universal but is clearly evident in an increasing number of markets – more so in urban and/or amenity-rich settings than in less affluent locations. For example, Thomas Tiemann (2008) provides a vivid depiction of the famous Pike Place Farmers' Market in Seattle, Washington, where souvenir-seeking tourist shoppers have neither the opportunity nor the inclination to know one another. In a similar vein, some markets in New Zealand have established strong links with wine tourism and the slow food movement as key components of their identity and attraction (Joseph et al. 2013). Indeed, on any given market day, there may be as much trade in cappuccino coffee and freshly shucked oysters as beans and potatoes! For some, such developments do not accord well with their vision of farmers' markets and their place in local food systems; for others this differentiation and distinction is essential. At a minimum, what is apparent is that the contemporary farmers' market is a diverse and multifunctional entity with a range of forms that defy easy or simplistic categorization. The same is true of its patrons.

The Meaning and Management of Authenticity

As the viability and visibility of farmers' markets continues to advance, there have been more concerted efforts in recent years to manage the brand. Front and center in this effort has been an attempt to frame the concept of authenticity as a core feature of "real" farmers' markets. As an entrepreneurial consideration, there is value in confirming and communicating the alterity of the farmers' market – establishing a difference that makes a difference (Kirwan 2004). From a strategic marketing perspective, the key points in defining alterity are usually (i) the opportunity for direct engagement with producers; (ii) access to local, fresh products in season; (iii) assurance of food

quality; and (iv) the ability to partake in the cultural capital attached to the market as a distinctly recognizable community institution. Such criteria are important as they not only form the basis for the constitution and organization of the farmers' market by local managers but also lead to the rules of conduct for vendors.

Recently it has been suggested that the issue of authenticity can be seen from both the "bottom up" and the "top down" and that this distinction helps explain some of the tensions seen at some markets. At the level of daily practice, individual markets navigate a series of issues relating to the simultaneous desires for diversity and regularity of food products, the building of consumer confidence concerning the provenance of food and the identity of the producer, the need to create a climate for business that provides adequate returns for vendor participants and the market itself, and an experience that meets the expectations of consumers. This both permits and even encourages diversity in the characteristics of farmers' markets as individual markets find their own comfort level in the presence of different types of producers and sellers of food – a situation that is welcomed by some and highly problematic for others. From above, it has been suggested that these complexities are too often dismissed in favor of an approach that seeks to impose uniformity as a way of guaranteeing success as a *real* farmers' market. Hence, there is debate in some quarters about whether or not flexibility should or does exist around some of these requirements and whether that flexibility threatens authenticity as a defining quality of farmers' markets (see, e.g., Smithers and Joseph 2010; Wittman et al. 2012).

Unfortunately the question of authenticity is not merely about semantics. At the level of farmers' market associations and at many individual farmers' markets, one of the most visible flashpoints seems to concern who *is*, and *is not*, a *real* farmer and thus a legitimate vendor with *authentic* local food. The concern in some markets is that the presence of the so-called resellers cheapens the brand and undermines the identity and validity of the entire venture. It is perhaps not surprising then that there have been recent attempts to more stringently define and even

regulate authenticity in relation to farmers' markets. Taken to its logical conclusion, the process of defining and verifying authenticity ends with the desire to regulate authenticity through formal certification – and indeed, this has happened in several jurisdictions including the United Kingdom and the Province of Ontario in Canada.

The concept of third party certification is, of course, fraught with complications and consequences of its own (Friedmann and McNair 2008). Inasmuch as certification has the power to confirm which markets are in compliance with requirements and thus "legitimate," the absence of certification has the potential to imply the opposite. The broad rationale for certification is well established and has been played out in detail in the realm of organic food. Its purpose is to provide assurance to consumers that the food product they are purchasing is what it purports to be – and to protect certified farmer-vendors from the fraudulent actions of competitors who may claim they are something they are not. Yet attention to the politics of certification in the organic farm sector also reveals that some organic farmers, notwithstanding their adherence to the principles and practices of organic (and related) agriculture, have elected to forego formal certification for a wide variety of reasons – sometimes in the conviction that neither they nor their food products require the bestowing of legitimacy from an outside authority whose *authority* they do not accept. It is precisely in this context that reports have emerged of a small number of farmers' markets in Canada and New Zealand actually braking away from a parent farmers' market organization – the dispute over legitimacy and a claim to the brand (Joseph et al. 2013). The process and protocols of certifying farmers' markets as *real* will make for interesting watching by both analysts and farmers' market actors in the next several years.

The Farmers' Market as a Community-Building Institution

The concept of third places has been invoked recently in relation to farmers' markets (Tiemann

2008). Third places are sites of informal association with opportunities for fellowship and exchange with diverse others. In North America the traditional general store has been seen historically as a third place. In Great Britain the same might be said about *the local* (i.e., the corner pub). More generally farmers' markets are seen as civic spaces. The inference is that they are public sites where community values are defined, shared, and debated and where community is "performed." They are community institutions with long histories in some regions – very short histories in others. But in both cases, they are a meeting place – places where products, people, and diverse personalities come together. In this sense, the farmers' market is often seen as much as a social phenomenon as it is an economic enterprise. Much international research into consumer experiences at farmers' market has confirmed that shoppers place the opportunity for meeting and associating with vendors and other visitors as being among the most important reasons for their patronage. This stands in sharp contrast to the experience of the grocery store. Indeed, some research has suggested that some shoppers actually place the opportunity for relationship building (often expressed as loyalty to specific vendors) ahead of some of the core authenticity attributes noted above. The term social capital has been invoked to describe this particular facet of the farmers' market experience. It is not that shoppers do not care about local or fresh or spray-free per se, but rather that these food attributes are sometimes taken for granted (sometimes even set aside) based on the trust accruing from valued relationships with particular vendors. Indeed, a few minutes of casual observation at virtually any farmers' market will be sufficient for most readers to spot these so-called *relations of regard*. Interestingly, they serve as both a strong rationale and a source of complication for ongoing efforts to define and regulate qualities such as authenticity and legitimacy in the actual performance of specific markets across North America and elsewhere. In other words, sometimes relationships trump rules.

The version of community noted above speaks to *communities of place* – local people making

connections with each other and, in so doing, building community. In a different vein it might be said that the farmers' market is seen as holding potential for linking various *communities of interest*. Two possibilities are noted but many others exist. It has been suggested that the farmers' market has at least the potential to form common ground for rural and urban interests and values and, by so doing, help alleviate the disconnect that some feel has arisen between these two sectors during the era of industrial agriculture and global food. The prospect of personal interaction between parties and the visible presence of diverse and differentiated food products provide a rare opportunity for eaters to learn about the challenges and realities of farming and growers to hear first-hand consumer perceptions (and perhaps misconceptions) about agriculture. Second, for many people, the farmers' market provides the opportunity to feel part of a wider change in the food system (Gillespie et al. 2007). As noted above, part of the farmers' market story is its differentiation from the conventional food system and its inextricable link to the local food movement. For an increasing number of people, the farmers' market has emerged as a place where consumption needs and personal values coexist comfortably.

Summary

The intention in this entry has been to both summarize and problematize the revival of the farmers' market as a key element in the growth of local and alternative food systems. They are places of commerce, consumption, community, and at times contestation. For farmers, the revival and now rapid growth of farmers' markets provides the prospect of capturing greater value and developing a different pathway for their enterprise. Consumers are extracting value in the form of food they trust, relationships they value, and the sense of supporting not only a food business but also a food idea – or perhaps more accurately a food ideal. Those on the governance side are working to define principles and guide practice. The contemporary farmers' market is a

constructed and complex space where philosophy and practice collide and where specific food choices reflect both values and accommodations. Uncertainties aside, it does seem that the farmers' market has reclaimed a place for itself on the food landscape with a future that will be interesting to watch unfold.

Introduction

The last 25 years has seen a paradigm shift in the understanding of the nature of knowledge and how it is exchanged in the agricultural context. A changing backdrop, with the move towards multifunctional land management, persistent environmental problems, and the search for sustainable agricultural approaches, has brought new challenges. At the same time, the research agenda on knowledge has changed as an era of positivism, during which science and scientific experts were

given unrivaled authority, were challenged by social studies of science that began to question the superiority of scientific knowledge, and value alternative forms of knowledge such as those held by farmers. Theory and practice of knowledge exchange in agriculture have evolved in line with this, shifting from a linear model of knowledge transfer to a perspective that integrates knowledge from multiple actors through facilitation and participation and emphasizes learning in a social context. The attention paid to knowledge within agricultural research is part of a wider consideration of contested knowledges and expert-lay divides and the democratization of expertise in science and environmental studies. These developments are indicative of wider changes in the rural development, natural resource management, and science in society perspectives and of changes that have taken place in intellectual debates, where postmodern concerns for pluralism have enabled marginalized groups to become stakeholders.

In the agricultural setting, the tensions at the interface between farmers and scientists have been the focus of much scholastic work, with attention given to how the two groups construct issues relating to agriculture (new technologies and sustainable agriculture), conservation, and environmental management and to how they communicate with each other. Farmer-science relations, specifically the *nature* of the knowledge they hold and the *processes* involved in the *exchange of this knowledge*, have provided a useful context for situating these discussions.

Nature of Knowledge

Scientific and Local Knowledge

A range of analysts have explored distinctive ways of knowing the world through elaboration of paired concepts such as codified/tacit knowledge, scientific/local, scientific/indigenous knowledge, expert/lay, and explicit/tacit. Terms such as local or indigenous knowledge have different connotations; however, they all indicate the types of knowledge that culminate through the experience of social groups embedded in specific

localities and cultural contexts. Scholars have typically juxtaposed such constructs against Western, scientific, instrumentally rational knowledge (Richards 1985) and extensively debated the epistemological distinctions between them.

Those critiquing scientific knowledge have emphasized its universal, objective, and decontextualized character. It is referred to as codified, expert, formal, standardized, institutionally legitimate, and explicit in that it can be systematized, written, stored, and transferred (Norgaard 1984). Understandings of scientific knowledge have been embedded in a realist-positivist perspective which regards scientific knowledge as produced through a process of reductionism, derived from data verified by independent observers under controlled conditions. According to this perspective, science is viewed as open, systematic, and analytical, advancing by building rigorously on prior achievements. The relationship with participants is regarded as detached, the methods are regarded as value-neutral, cases are treated as representative rather than having intrinsic value, the approach is deductive, and the aim is to develop predictive criteria that provide a basis for universal and context-free generalization.

With respect to knowledge exchange, as discussed below, scientific knowledge is regarded as discrete, tangible, and transferable.

The term 'local knowledge' came from the international development and anthropology literatures. Such knowledge has been described as fundamentally linked to direct experience and the practical, sensuous, and personal skill that develops with attention to a specific place. Scholars have emphasized the attributes of local knowledge that distinguish it from scientific knowledge, describing it as closed, non-systematic, and holistic rather than analytical and without an overall conceptual framework, advancing on the basis of new experiences, not on the basis of a deductive logic. Where science is regarded as universal, local knowledge is strongly rooted in place, anchored to a particular social group in a particular setting at a particular time. Due to its tacit nature, local knowledge is seen to rely on social processes for knowledge exchange.

Criticism of Scientific Agriculture

Over the last 25 years, criticism of scientific agriculture, in particular focusing on the authority given to scientific knowledge and the neglect of local forms of knowledge, has emerged as a strong force within both developing and developed countries. Scholars point to science's privileged role in the development of agriculture and agricultural policy in Western countries, particularly in the post-war period, as scientists were charged with modernizing agriculture and increasing food production. Critics have argued that there was an assumption of superiority of scientific knowledge developed in controlled research settings over knowledge developed through practice in less controlled settings as on farms. They consider that the status accorded to scientific knowledge, by virtue of its rigor, systemic approach, and rationality, effectively allowed science to stand apart from other knowledge systems and enabled science to be the standard paradigm against which all other forms of knowledge were to be assessed. Philosophical perspectives on science and its dominance come from scholars who argue that science constitutes institutionalized power because scientists impose a system of ordered procedures for the production, regulation, circulation, and operation of statements.

Consequently, scholars argued that non-institutional forms of knowledge, perceived as lacking the rigor, rationality, and logic of science and categorized as backward, primitive, irrational, or parochial, have been ignored, marginalized, or underrepresented in society as a whole and specifically in agriculture. As such local farmer knowledge in both developing and developed countries was seen as being denied legitimacy. This criticism is aligned to debates about expert and lay knowledge where the deficit model of scientific understanding deems non-scientists ignorant when it comes to scientific and technical matters and where lay knowledge is assessed and judged from the scientific point view. In the environment management context, similarly policy makers are described as using the discourses of certainty and technical expertise to maintain their privileged status as legitimate arbiters of environmental standards (Whatmore 2009).

As part of the criticism of agricultural science, it was argued that, as scientific knowledge and practice were applied in new situations, the complexity which has co-evolved in many areas over long time periods between local agricultural practices and local natural environments was often destroyed (Kloppenburg 1991). Scholars, particularly those from the Wageningen School, have documented this displacement of local knowledge and cultural practices by 'alien' scientific techniques (Long and Long 1992). With this, displacement science was seen as a new form of colonialism, and for some commentators, this imposition of Western scientific knowledge explained why development had become unsustainable. Debate about the disregard for local knowledge was not restricted to developing countries. A seminal study by Wynne (1996) in England documented how, in the aftermath of the Chernobyl nuclear disaster in 1986, scientists ignored local farmers' knowledge in their research in the Cumbrian hills to find out how to protect sheep from radioactive contamination.

The Rise of Local Knowledge

These criticisms and debates heralded a shift in thinking about traditional knowledge. Whereas previously many theorists regarded it as an obstacle to development, today indigenous knowledge is seen as pivotal in sustainable resource use and development predominantly in less industrialized countries. In works such as Richards' *Indigenous Agricultural Revolution* (1985), researchers have attempted to validate the existence and utility of indigenous knowledge systems. The Farmer First movement launched in 1987, which questioned the scientific "way of knowing" as an appropriate model for future sustainable development and for the extension of democratic principles, was a landmark in this shift towards valuing farmers' knowledge (Chambers et al. 1989) and heralded two decades or more of farmer-centered research and development in international development. Central to this rediscovery of the concept of local knowledge was the continued critical examination of the impacts of orthodox science. The body of work grew documenting farmers' local knowledge of soils, pests, varieties, etc. This work

claimed that farmers have an intimate and intuitive knowledge of their farms and a refined understanding of local spatial and temporal processes, gained through years of walking and cultivating the land. This work has also shown that local knowledge is, characteristically, related to use rather than the standardized categorization criteria derived from science.

In the Western world, local knowledges have long been denied a legitimate status. Since the 1990s, however there has been growing interest in farmer knowledge in developed countries fueled by debates about the epistemological distinction between local and scientific knowledge systems, the changing role of farmers and scientists in research and extension, and the need for environmental and social change. In the context of economic crises in agriculture, environmental pollution, agribusiness domination, and concerns about food quality, it was considered that new insights and perspectives which valued alternative knowledge forms were needed. Exponents of this view also agreed that local knowledge, being more ecosystem-sensitive and context-dependent, was more relevant to sustainable practices than decontextualized scientific knowledge. As such the term 'local knowledge' entered the sustainability discourse in developing countries. A number of studies have demonstrated how sustainable knowledge and practice have developed outside of conventional knowledge systems, for example, Kloppenburg's (1991) analysis of rotational grazing in Wisconsin, USA.

The changing attitudes towards, and relevance of, local knowledge are apparent in the increasing number of research, development, and management models that include farmers as active participants and knowledgeable stakeholders. However, as interest has turned to farmers' knowledge as part of resource management and environmental disputes, this has highlighted the contentious nature of the relationship between local and scientific knowledge (Whatmore 2009). Authors have described the way in which farmers draw on context-specific experiential understandings in completing their practices and how these understandings can conflict with, and are negotiated alongside, those understandings embedded within

science, with technologies, and with conservation practices (Eshuis and Stuiver 2005).

Advocates of farmers' knowledge, however, have been criticized as naive and guilty of distorting and exaggerating its value while neglecting its limitations. Critics warned against mythologizing local knowledge suggesting that it can often be nothing more than a set of improvisational capacities summoned by needs (Molnar et al. 1992). With respect to the argument that local knowledge is sustainable knowledge, critics point to the fact that some indigenous people in fact degrade their own land. Scholars argued that scientific agriculture may be just as capable as local knowledge of finding sustainable solutions. Indigenous knowledge, although still of great value in developing countries, is thought to have no relevance to modern Westernized agriculture where farmers have come to rely heavily on scientific applications in agriculture.

These debates have culminated in an acceptance that it is unhelpful to reduce the discussion to one that distinguishes scientific or local knowledge as the "right" or "wrong" sorts of knowledge and that instead there is a need to understand the processes that bring about integration of different knowledges.

Knowledge Processes

Over recent years the concept of knowledge in the singular has been increasingly challenged by ideas of differentiated, contextualized knowledges. Debates about the dichotomy between local and scientific knowledge and their respective values have led many researchers to criticize this categorization and argue that conventional distinctions between the two no longer hold. It has been argued that these knowledge forms are fundamentally complementary, that knowledge is composed of blends of all knowledge forms, and that it is heterogeneously constituted (Long and Long 1992). Equally others have suggested caution should be exercised in the use of prefixes such as 'expert' and 'lay' when talking about knowledges as this strengthens the processes keeping them apart.

The distinctiveness of different forms of knowledge has also been challenged within the

social sciences where there has been a growing conviction that knowledge is the outcome of social processes. Sociological interpretations of science challenged ideas about the distinctiveness of scientific knowledge, and ideas by Knorr-Cetina (1981) were developed in a number of empirical studies that followed. These have shown that science is socially constructed in a specific location and as such is achieved in much the same way as other kinds of knowledge. As a consequence social scientists have argued that the distinction between universal knowledge and local knowledge is weakened. There has also been support for theoretical criticisms of what has been called the “rise of indigenous knowledge” which argues that the classification into indigenous and Western knowledge fails because there are not only similarities across these categories but also differences within them. This science philosophical approach is called social constructivism and has become a main paradigm from which many social scientists analyze the role of knowledge. However, as with distinguishing forms of knowledge, other academics have argued that it is better to integrate this social-constructivist view with the positivist approach of knowledge development which aims at finding measurable parts of reality to validate knowledge claims.

Given these theoretical and philosophical arguments, many scholars have concluded that it makes much more sense to describe knowledge, not as a fixed thing, but as fluid and changing, the outcome of a set of processes where social processes are central (Murdoch and Clark 1994; Scoones and Thompson 1994).

Knowledge Exchange

There has been increasing emphasis on the need to find effective ways of exchanging knowledge between farmers/land managers and the many actors they interact with to enhance sustainable agriculture and environmental management. Many different terms are used to describe knowledge exchange processes; these include knowledge sharing, generation, co-production, co-management, transfer, brokerage, storage, exchange, transformation, mobilization, and

translation, but knowledge exchange can be simply understood as constituting the processes that generate, share, and/or use knowledge through various methods appropriate to the context, purpose, and participants involved. While early models of knowledge exchange focused on linear processes of knowledge production and consumption, a shift towards more systemic approaches provided frameworks for understanding knowledge exchange as multiple processes operating between multiple actors (Roling 1992).

As with the nature of knowledge, the last 25 years has seen major debate and changes in thinking about the knowledge exchange processes in the agricultural context. This is the main part that has been undertaken within the discipline of agricultural extension, both scholastically and in practice, although contributions have come from a number of other disciplines including environmental management, rural sociology, development studies, and communication science. These have all tended to highlight issues such as legitimacy of different knowledge forms, inequality, and power dynamics, including the effect of relative position or status of those generating and using knowledge.

Knowledge Transfer Models

In the agricultural extension literature, it is possible to document an evolution in theory and practice from persuasive knowledge transfer approaches to more facilitative human development perspectives (Roling 1992). Theory and methodology have traditionally been predicated on the promotion of technological innovations with a reliance on the top-down, unilinear model of transfer from science to practice (the knowledge transfer model). This notion of a one-way path was developed and adapted by a number of authors, the most pervasive being Roger's (1995) diffusion of innovation theory and the technology transfer (TOT) model which has underpinned the activities of many extension services and development activities. The large literature on adoption of innovations has been reviewed in general (Rogers 2003) and for extension (Black 2000). This knowledge transfer

approach is analogous to the technical-rational model of policy development. The knowledge transfer paradigm as the dominant model of knowledge production in conventional agriculture captured the concerns of the so-called productivist era of the 1970s and 1980s in industrialized countries when the focus was on food production (Buttel 2001). However, it has since been found limiting.

Academics from rural sociology within the USA and European schools of international development argued that, because the model was embedded within realist-positivist theoretical view of scientific knowledge (seen as a discrete, tangible entity which can be transferred between actors), it did not accord with new interpretative views of knowledge, as discussed above. They also argued that the uni-linear approach failed to represent the many different sources from which knowledge is generated and that it was irrelevant to modern agriculture, which has multiple goals and demands more stakeholder negotiation and agreement. Concerns were raised about equality specifically with reference to the adoption/diffusion model which ignored many of the important social issues such as the unequal distribution of impacts and benefits of the technology, as the service provided by the extension agencies reached, differentially, the better educated and more economically powerful farmers. Those adopting new technologies were seen as ‘innovators’ and held in high regard, while those not adopting (and/or rejecting) new technologies were labeled as ‘laggards’ and viewed disparagingly. This dominating techno-strategic discourse according to critics such as Kloppenburg (1991) assumed that farmers had nothing to contribute; their knowledge and skills were marginalized and discredited. Agricultural extension was seen in these terms as espousing, uncritically, pro-corporate ideology and was criticized as being the handmaiden of the scientific-industrial agribusiness complex in that it accepted that all farming problems could be overcome by the continued application of conventional science. Furthermore, research institutions were also criticized as developing technologies that were not value-neutral and often resulted in creating greater social and

economic inequalities. Thus, the knowledge transfer approach to science as the domain of knowledge elites was seen as problematic for the inclusionary ethos of the human development paradigm.

Human Development Approaches

These criticisms have led to the waning of this dominant paradigm in research and theory and to the formulation of human development approaches based on the principles of participation, empowerment, and ownership of the problem. Increasing interest in multifunctional land management – a general challenge to technocracy and scientific superiority – persistent environmental problems, and the need to develop more sustainable agriculture provided the backdrop for this paradigm shift. With human development approaches, the implication was that, given the right conditions, information, mutual interaction, and opportunity, land managers will use their own knowledge and develop their own appropriate solutions to their problems. These approaches view the extension process as facilitation of social learning, a philosophy focusing on participatory processes of social change. They give validity to expert and non-expert forms of knowledge and are thought more likely to lead to adaptive forms of environmental management and longer-lasting or more effective outcomes. Scholars also argue that such approaches are particularly suited to understanding the transformation towards more sustainable agriculture, a process that they thought to require mutual interaction between actors. The Wageningen School (Roling 1992; Roling and Wagemaker 2000) was central in providing theoretical conceptualizations to underpin these developments and in using systemic approaches (Agricultural Knowledge Systems) as frameworks for understanding the multiple actors and processes of knowledge exchange they were involved in. The human development approach is analogous with theories of negotiated knowledge in the broader field of deliberative governance, whereby intersubjective judgment is regarded as essential to effective decision making. This paradigm shift reflects wider changes in the disciplines of rural and

development sociology and rural geography during the 1980s and 1990s where culturalist or subjectivist views emerged in a post-Marxist era to counter the perceived determinism of political economy.

Agricultural research and extension organizations have, to a varying degree, become involved in various human development approaches. Research and development in developing countries embraced participatory methodologies such as the farming systems approach (FSA), participatory rural appraisal (PRA), and participatory technology development (PTD). Chambers et al. (1989) were the early exponents of these participatory approaches. These approaches have been reviewed extensively (see Garforth and Usher 1997; Black 2000). In extension, Farmer Field Schools, where participatory training and hands-on experimentation are a key principle, gained prominence in many developing countries. Scholars and policy makers have also documented a number of cases which exemplify effective facilitation of farmer learning, such as the Australian Landcare initiative and farmer learning groups in the Netherlands.

Although seen as an improvement on the failings of the knowledge transfer model, scholars have voiced a number of criticisms of human development models and methodologies. These have been divided under five main themes (Black 2000): firstly, the lack of a coherent theoretical foundation; secondly, the lack of attention to issues of legitimacy, accountability, and representation; thirdly, the problems associated with poor participation practices; fourthly, the difficulties and dangers in working with multiple forms of knowledge; and finally, the political dangers inherent in shifting responsibilities from the state to civic society. Issues such as the professional identity of scientists, the skills base and available human resources, and perceptions concerning the validity of research methods have arisen in practice. Most researchers argue that participation involves ensuring the knowledge and views of people that are more equitably incorporated in decisions and consider that this requires managing and reforming the power relationships.

Summary

Today there is recognition that sustainable agriculture, which encompasses balancing agricultural production with elements such as ecosystem protection, the continuing supply of natural resources, and the well-being of rural communities, needs to be supported by diverse knowledge systems which draw on both local and scientific knowledge. In policy circles in industrialized countries, the language and discourse are changing from one of knowledge transfer to one of knowledge exchange which is seen as a key device for achieving change in the agricultural context, particularly where voluntary participation for environmental protection is encouraged. However, issues still remain in effectively implementing knowledge exchange such as how to evaluate the outcome of knowledge exchange activities, how to accommodate different cultures, how to deal with power relationships, and how to develop effective techniques and tools (Fazey et al. 2012).

In agricultural development arenas, the social and political dimensions of knowledge generation and exchange remain the focus of interest but with a move towards improving understanding of knowledge entrepreneurship and marketing, knowledge brokerage, governance and networks and alliances which can reconcile the needs of scientists and of locals through new forms of equitable collaboration which go beyond what some observe to be the somewhat “tired discourse of participation” (Scoones and Thompson 2009). The debate has moved on from a concentration on the interaction between farmers and technologies/science to incorporate wider perspectives of institutional change. The concept of the Agricultural Innovation Systems is becoming popular as a way of framing the processes of networking and interactive learning among a heterogeneous set of actors, which go beyond knowledge producers and consumers.

Introduction

The industrialization of agriculture has created a farm structure where a small percentage of large farms account for a large percentage of sales and a large percentage of small farms account for a small percentage of sales. In general, these large farms produce for indirect global commodity markets, while the small farms participate in direct sales markets. In between are the shrinking mid-sized farms that are too small for commodity markets but too large for direct markets. While explained by some scientists as progress and supported by productivist perspectives of agrifood production, the industrialization of agriculture has important negative implications for the quality of life in rural communities in particular and society in general. This entry applies a Sociology of Agriculture conceptual frame to the case of the changing structure of agriculture in the USA to inform discussions regarding ethical dimensions of the industrialization and

globalization of the agrifood system. First, the information and data regarding changing farm structure are reviewed. Next, the salient Sociology of Agriculture literature is presented to context and evaluate the data. Finally, a summary is provided.

The Data on Farm Structure and Size

Farm numbers decreased as average farm size increased during the twentieth century. In 1945 there were over 5.8 M farms, with an average size of 195 acres; in 2002 the total was just over 2.1 M farms averaging 441 acres. From 2002 to 2007, the number of farms increased by 75,810, with a stabilization of farm size at 400+ acres. Most of this growth came from an increase in small operations; farms with \$1000 in sales or less increased by 118,000, while those with more than \$500 K in sales increased by 46,000. The mid-sized operations decreased. US agriculture is characterized by a dual structure whereby a few very large farms have a large percentage of sales and many small farms have a small percentage of sales. In the 2007 Census of Agriculture, the only farm categories that increased in number were the smallest (less than 2.5 K sales) and the largest (more than \$500 K sales) (USDA 2012).

Total agricultural sales increased significantly from \$200.6B in 2002 to \$297.3B in 2007. Commodity sales are ranked: cattle/calves (20.6%), corn (13.4%), poultry/eggs (12.5%), milk/dairy (10.7%), soybeans (6.8%), fruits/nuts/berries (6.3%), hogs/pigs (6.1%), nursery/floriculture (5.6%), asst. fruits/veggies (4.9%), and others (12.0%). The largest operations increased their share of production from 2002 to 2007. Farms with more than \$1 M in sales increased their share from 47% to 59%. The number of farms that accounted for 75% of total sales decreased from 144 K to 125 K farms. Using the USDA typology, large family farms (\$250–500 K sales) and very large family farms (greater than \$500 K sales) made up 9% of farms but accounted for 63% of sales. The larger the operation, the less likely it engaged in off-farm work and more likely it hired labor and received government

commodity payments. These data from the 2007 Census of Agriculture confirm the continuation of a trend toward more small and very large farms and fewer mid-sized farms (USDA 2012).

The steady decline in the number of small farms stabilized in the 1992 Census. In 2007 small farms made up 91% of farms and accounted for 37% of sales. All of the increase is at the bottom of the “small farm” category (less than \$10 K sales). At the high end, farms with sales between \$100 K and \$250 K decreased by 7%. Using the USDA typology, the high percentage of “residential/lifestyle” (36%) combined with “retirement” (21%) and “limited resource” (12%) types of small farms are increasing, but the “farming occupation/lower sales” (11%) category is decreasing. Keeping in mind the differences in the small farm category, small farms tend to rely on off-farm income, not hire labor, not rely on government commodity payments, but do rely on government transfer payments (such as social security). The higher end in sales are commercial operations, just smaller; the lower end in sales are noncommercial, in that there are usually other forms of income. The groups in the middle (\$10–100 K) are the most likely to engage in direct sales (USDA 2012).

Direct sales operations tended to be small farms with less than \$250 K sales. The number of direct sales farms increased by 17.2% to 136,817 farms, but accounted for only \$1.21B in sales (of the total \$297.2B), only 0.4% to total farm sales. The limited resource, retirement, and residential/lifestyle types accounted for 93.3% of direct sales. A majority of “new farms” are smaller and also rely on off-farm income. Since the 2002 Census, 291 K new farms started operations. New farms tend to be about ½ as big as national average (201 vs. 418 acres; \$71 K vs. \$135 K in sales). The small and new farmers tend to report that farming is not their primary occupation (USDA 2012).

In summary, the consolidation trend continues as the largest operations gain market share. But there is also growth in the small farm category linked to new farms and direct sales. The mid-sized farms continue to decline in numbers. There also appears to be a stabilization of average farm size.

The Discourse on Farm Structure and Size

Previous to the 1970s, discussions about farm structure and size were couched in a functionalist language that saw the growth of large farms as a natural evolution of economies of scale and a specialized division of labor. The adoption-diffusion framework was embraced uncritically assuming that the implementation of scientific agriculture based on technological innovations improved efficiency and enhanced the quality of life for society. Technologies such as machinery, synthetic fertilizers, and pesticides allowed agriculture to break free of the historical metabolic constraint that limited farm size. As long as animals were the primary source of fertility for crops, farm size and crop specialization were constrained. Synthetic fertilizers, combined with synthetic pesticides, allowed large-scale monoculture and rapid advancement of industrial agriculture and farm size.

Any negative impacts on rural communities were interpreted as creative destruction as simple social systems based on moderate-sized diversified operations evolved into large-scale specialized operations. It was the Land Grant University system’s mandate to modernize agriculture by providing public education to the common people and then extending that research and education to farmers. Progressive farmers should adopt the technologies for the benefit of society. Social movement activity and concerns about rural quality of life prompted the US government to pass legislation during the New Deal Era to support family farms with subsidies. Even as agrarian social movements attempted to stem the tide of industrial agriculture, the modernist project was solidifying its institutional agenda in the Land Grants, USDA, agricultural committees in Congress, and commodity organizations. From the industrial perspective, science and industrial agriculture were about to end world hunger and develop all nations.

Although scientific agriculture generated a huge increase in productivity per acre, in the 1970s this productivist paradigm came into question as the unintended consequences and negative

externalities of industrial agriculture became apparent. Rural social scientists embraced critical frameworks to interpret the impacts of industrial agriculture on rural America. A *Sociology of Agriculture* literature was rediscovered and enhanced. First, the ecological crisis of industrial agriculture manifested in the form of ecosystem degradation, particularly the effects of chemical-intensive agriculture. The productivity gains, and associated profits, were subsidized by externalizing costs onto the environment. This crisis generated a literature that addressed the Environmental Question: What is the relationship between industrial agriculture and environmental quality? Political ecology perspectives (Buttel 1987) exposed industrial agriculture as an extractive, chemical-intensive, monoculture system with negative impacts of soil erosion, water quantity and quality degradation, species depletion, and pest resistance. While industrial agriculture increased productivity and lowered food costs, the metabolic rift removed animals as the source of crop fertility and thereby generated unintended environmental consequences. This research documented that industrial agriculture was unsustainable ecologically.

Second, a *Sociology of Agriculture* literature emerged in the 1980s around the Agrarian Question (Buttel and Newby 1980). The Agrarian Question asks: What is the relationship between the structure of agriculture and the quality of life in rural communities? The Farm Debt Crisis of the 1980s accelerated the historical trend (noted above with USDA data) of a bifurcation of agriculture into a small percentage of large farms that produce most of the agrifood commodities and a large percentage of small farms that produce a small percentage of the foodstuffs. The mid-sized farms were disappearing. Large farms linked to global commodity chains found themselves on a technology and debt treadmill that forced them to expand acreage to capture decreasing per acre profits, while smaller operations were either forced out of farming or relegated to the margins as hobby farms. Mid-sized family farms survived through super-exploitation of family labor and off-farm income. Rural communities made up of mid-sized farms

were often decimated in the process of farm consolidation (Magdoff et al. 2000).

As the Agrarian Question gained traction, a political economy of agriculture perspective rediscovered the works of Walter Goldschmidt (1947) on the relationship between farm structure and community quality of life. Those studies revealed that middle-class, family-farm systems of agriculture contributed to a higher community quality of life than industrial systems based on absentee ownership and hired labor. The Goldschmidt findings were supported by recent research (Lobao 1990; Lyson 2004). During this time the works of Aldo Leopold and Wendell Berry provided an alternative philosophical position grounded in Jeffersonian Agrarianism. While many in the agricultural community, such as agricultural economists at the Land Grant Universities, the commodity associations, and the USDA, continued to support industrial agriculture, the legitimization crisis was building as farmers and environmental organizations criticized industrial agriculture as unsustainable.

Guided by the Agrarian Question, rural social scientists investigated the impacts of farm size and structure on rural quality of life. While one has to be careful not to conflate size and scale, they are often related. Farm structure refers to the ownership pattern in agriculture. For example, is the structure based on independent producers (family farmers), contract farmers (such as in poultry or hogs), or corporate farms (separation of ownership and management/labor)? As noted above, following Goldschmidt and others, a middle-class, family-farm-based system of agriculture made up of independent producers supports rural quality of life. Contract farming is seen as an intermediary step toward a corporate structure, where integrators control the labor process without direct ownership. Family-farm systems of agriculture create a more vibrant community system that generates social capital, community attachment, and socioeconomic development. As agriculture moves from an independent to a corporate structure, there is a weakening of community attachment and a transfer of wealth from the producer to the corporate shareholder, decreasing the quality of life in rural areas. Additionally, farm

structure includes the relationship between the farm operation and the input and output markets. Agribusiness vertical and horizontal integration accelerated in the 1980s leading to input and processing oligopolies. Farmers were increasingly at an economic disadvantage as they bought from and sold to concentrated markets (Heffernan 2000). The ecological metabolic rift made possible by industrial agriculture also generated negative impacts on rural social well-being.

Farm size, as measured by gross sales, intersects with structure as the larger operations sell a few undifferentiated commodities in indirect markets in the global agrifood system. Many of these operations are family-owned but are incorporated due to their large size (USDA typology: large and very large family farms). These large operations, both family-based operations and corporate, are linked to agrifood TNCs through commodity chains, increasingly “driven” by large retailers such as Walmart and McDonald’s. With the increasing globalization of the agrifood system, these operations compete as lowest-cost producers in global commodity chains and again find themselves caught between powerful input (fertilizer, pesticides, and seed) suppliers and processing corporations (wheat, soybean, corn, meat) such as ADM, Cargill, JBS, Monsanto, and Tyson (Magdoff et al. 2000). A caveat is needed here. Not all large farms are large in size of acreage. Fresh fruit and vegetable operations can be small in size but large in sales and still tend to produce for commodity markets. Furthermore, these operations rely heavily on farm labor, often undocumented, which returns us to negative community impacts of the Goldschmidt findings.

The legitimization crisis associated with negative impacts of industrial agriculture also reached consumers. The Food Question asks: What is the relationship between industrial agriculture and the quality of the food we eat? Consumers and producers are concerned about the poor quality of the highly processed industrial food. Concerns about animal welfare, pesticide contamination, antibiotics overuse, *E. coli* and salmonella, and an “empty calories” diet generated a demand for healthier food, referred to as the “quality turn” in agrifood studies. Consumers want scientifically

grown food, but want it grown reflexively, with more concern for the ecological, social, and economic impacts. The fact that sustainable agriculture is discussed in the mainstream validates the crisis of industrial agriculture (Allen 2005). This body of research documented that industrial agriculture was unsustainable socially.

Small farms became the site to produce this healthier food. Beginning with the organic movement, small agro-ecological producers became linked to political consumers and began to build an alternative agrifood system (Guthman 2004). This alternative agrifood movement expanded to include community-supported agriculture (CSA), Slow Food, farmers markets, Chef’s Collaboration, fair trade, farm to institution, agritourism, and Agriculture of the Middle (Morgan et al. 2006; Hinrichs and Lyson 2009). Small farms tend to operate in direct-sale value chains that support social capital and retain more wealth in the community.

Some explanation is necessary. Commodity chain analysis (Gereffi and Korzeniewicz 1994) identifies which actors along the supply chain generate value and drive the chain. Those actors who drive the chain tend to capture a disproportionate share of the value along the chain. For example, undifferentiated commodity chains, such as number 2 yellow corn, include thousands of producers and a few large input suppliers and processing firms. Most of the value in the chain is generated by the producers through their labor value, but because the corporations “drive the chain,” they extract a greater share of the value due to their market power. Commodity chain analysis reveals that it can be hazardous for farmers to attach themselves to global commodity chains where they are sourced as low-cost suppliers. As mentioned above, these operations must expand and capture economies of scale to survive in concentrated markets linked to food retailers that increasingly drive the global commodity chains.

Supporters of alternative agrifood systems delink from this commodity system and operate in value chains based on identity preserved and/or direct sales. Value chains return a higher proportion of the value to the producer. Organics provided the ecological basis for this system

(Guthman 2004), and fair trade provides the ideological underpinnings (Raynolds et al. 2007). Organics is a value chain where producers are rewarded for ecological production. Fair trade is an attempt to create transparent and cooperative relationships that reveal where the value is generated and apportioned along the chain. It began as a way to link producers in the global South with consumers in the global North and eliminate the corporate middlemen that extracted an unfair share of the value along the commodity chain. Coffee and bananas are early examples of the fair trade initiative. Fair trade repossesses the value that was taken by the corporate drivers of the commodity chains.

Agricultural ethicists have provided a philosophical framing of these dual agrifood systems (Thompson 2010). The industrial perspective sees agriculture as just another part of industrial society where commodities are produced at the lowest cost; the trend to consolidation is just economies of scale at work to lower cost. This system must be exported to ensure sustainable food production for the world. Landscapes are viewed in terms of the commodities they can produce, and while there are some concerns with labor, community, environment, and animal welfare, these externalities can be addressed. From this view, sustainable equals produce more with less. The agrarian perspective views agriculture as having important social functions beyond efficient commodity production, such as providing ecological services and ecosystem functional integrity. Agriculture should be embedded in the local community, and consolidation negatively impacts the sustainability of local community quality of life. This view includes arguments of fair trade, fair labor, and animal welfare and asserts that a major departure from industrial agriculture is needed because that model is extractive and not sustainable.

Summary

The USDA provides interesting data to engage the Sociology of Agriculture literature. There is a dual agriculture in the USA with a few large farms

dominating sales in global markets and numerous small farms expanding direct sales at the local/regional level. These trends are both concerning and encouraging. Industrial agriculture is problematic for many rural communities. Where agriculture is an important component of the economic base of a region, the quality of life in rural America is influenced by the size and structure of agriculture. Farmers and communities linked by agrifood corporations to global commodity chains are in precarious positions where the firms driving those chains can use their market power to extract surplus value along the chain and whipsaw them as lowest-cost producers. Arrangements that benefit the commodity farmers are temporal; vertical and horizontal integration will push toward economies of scale and lowest-cost producer survival. Corporate quarterly return on investment drives the global commodity chains. Because of its market power and profit logic, it often extracts instead of contributes to wealth in rural communities. The technological focus maintains the productivist approach as the industrial model is diffused globally.

It is encouraging that the beyond organic system of smaller-scale agrifood production has expanded to include thousands of CSAs, multiple food to institution initiatives, an explosion of farmers markets, and a Slow Food movement as part of a local-food resurgence. The USDA data presented above quantifies the growth of small farms and direct sales that support these local and regional agrifood systems. Food policy councils have emerged to provide a governance function to the alternative agrifood movement. The region is the optimal unit of analysis as it is big enough for some economies of scale for Agriculture of the Middle producers and small enough for relationship marketing by smaller producers. Informed by civic agriculture, the optimal model is regional fair trade value chains with governance provided by regional food policy councils. This reflexive form of agrifood production acknowledges the mistakes of the past associated with uncritical adoption of agricultural technologies and attempts to internalize the externalities through the creation of sustainable agriculture (Allen 2005; Beck 1992).

Following the agrarians Leopold, Goldschmidt, and Berry, the erosion of agrarian values accompanied by the ascent of industrial philosophy and declining social well-being has been traced (Thompson 2010). A distancing from the roots of agrarian culture grounded in land, hard work, own boss, and community creates selfishness and decreased quality of life. Industrial values create instrumental over substantive forms of rationality, a focus on maximizing self-interest in econometric relationships with little concern for the public good. To fix the problem, farmers, rural communities, and citizen consumers should delink from the global agrifood system and create sovereign agrifood systems based on agrarian philosophies and civic agriculture. Building upon civic agriculture (Lysen 2004) as the production model, a “culture of the table” is a place where people can rebuild agrarian values (Borgmann 2006), a place where stories about where the food came from are told slowly and substantively.

Transformative change is needed to make the agrifood system sustainable (National Research Council 2010). Alternative agriculture is the transformative dimension. Re-embedding agriculture in community through local and regional agrifood systems organized as regional fair trade value chains can revitalize parts of rural America. While currently only a tiny fraction of total agrifood production is accounted for by alternative value chains, there is substantial movement in this direction. The small farms expansion in the USA is part of the growing resistance to industrial agriculture, part of the global food sovereignty movement for farmers, consumers, and indigenous peoples (Wittman et al. 2010). The alternative system is diffusing across the USA and the world, and rural social scientists should provide support to the movement. The discourse on sustainability around food security (industrial) and food sovereignty (agrarian) models provides teachable moments. Food sovereignty movements such as Via Campesina are social justice movements. They challenge the neoliberal restructuring of civil society in favor of capital over people (Harvey 2005). The fourth question in agrifood studies, the Emancipatory Question (Constance

2008) asks, “What is the relationship between industrial agriculture and social justice?” An ethical agrifood system would minimize environmental, economic, and social forms of injustice.

Organics engages the environmental injustice dimension. But conventionalization has blunted the early transformative dimensions of organics, as evidenced by the trends toward larger operations using hired labor and organic input substitution practices to produce for global commodity markets and plus market consolidation (Guthman 2004). The small farms movement has potential to avoid market power dimensions and allow producers to get fair value for their production. Fair wages for farm labor are a more difficult dimension. Local food is surging, but local may include unethical dispositions to racism or sexism. The class dimension of quality foods also has to be resolved.

Although many of the actors participating in the alternative agrifood movement are not informed by agrarian values, such as the pragmatic conventional farmers growing organics, their actions are creating the desired result. There is movement in a more ethical direction for the agrifood system, and small farms are leading the way. This movement is encouraging for ecological, economic, and social sustainability and quality of life.

Farmworker Rights

Clement Loo

Environmental Studies, University of Minnesota,
Morris, Morris, MN, USA

Synonyms

Farm labor conditions; Farm labor rights; Farm-worker unionism

Introduction

The scholarly conversation about farmworker rights tends to be concerned with fair wages, workplace safety protections, and protecting those working within agriculture from threats, violence, or forced labor (Loo 2014; Weissman 2010; Gottlieb and Joshi 2010). Indeed, several of the worst disparities within the global food system involve how farmworkers are treated by their employers (Loo 2014). Farmworkers are consistently poorly paid, overworked, labor under dangerous conditions, mistreated by their employers, experience employment insecurity, and are often de facto slaves (Loo 2014).

Within California, which sells an average of \$35 billion of agricultural products per year, the average farmworker only earns between \$5000 and \$8500 per year (Brown and Getz 2011) and, though they work in one of the most agriculturally productive regions within the United States, over half are food insecure (Minkoff-Zern and Getz 2011).

Employment insecurity and inconsistent hours add to the challenges associated with low wages (Brown and Getz 2011). Agriculture is a seasonal sector that requires labor only intermittently. With increased use of herbicides, pesticides, and automation—weeding, irrigation, and other maintenance of crops requires many fewer hours of human labor. As such, most farmers only need the assistance of farmworkers during planting and harvest. So, while farmworkers will work an average of 28 hours-a-week during the 34.5 week growing season, this work is not evenly spread through those weeks; farmworkers tend to work extremely long hours at the beginning and the end of the growing season but often need to find supplemental work in the interim (Loo 2014).

Farmworkers are also routinely exposed to agricultural chemicals (Gottlieb and Joshi 2010). Due to these exposures, farmworkers experience elevated rates of sterility, birth defects within their children, asthma, Parkinson's disease, and cancer (Gottlieb and Joshi 2010; McCauley et al. 2006). These elevated rates of disease are often made worse by limited access to health insurance and healthcare.

Scholars who are interested in addressing the problems listed above tend to focus upon two topics: (1) the factors – particularly racism and immigration status – contributing to the poor conditions for farmworkers and (2) the role of labor organizing in improving those conditions.

The Role of Race and Immigration

Within the United States, the issue of farmworker rights – at least since the twentieth century – has been inextricably tied to race and immigration. Some estimates suggest that approximately 90 % of farmworkers presently working within the United States are undocumented immigrants from Asia and Latin America (Gottlieb and Joshi 2010). Moreover, the reliance of the agricultural sector upon immigrants who are people of color for labor is not a recent occurrence. The US Department of Labor (DOL 1945) acknowledges that agriculture in the United States has been reliant upon immigrant workers since the mid-nineteenth century.

Yet, despite their long history within American agriculture, immigrant farmworkers are routinely subject to mistreatment. Often this mistreatment is directly the result of racial discrimination. A clear example of this can be found in the treatment of immigrant Chinese farm labor throughout the mid- to late-nineteenth century.

Substantial Chinese immigration to the United States began with the Gold Rush in the 1850s (Minkoff-Zern et al. 2011). Anti-Chinese legislation late in the decade made it impossible for these immigrants to continue mining and prospecting (McWilliams 1935). As a result of this, many of the Chinese who had initially worked in mines and mining camps began to work as farm labor (McWilliams 1935). According to the US Department of Labor (DOL 1945), the influx of Chinese workers was viewed favorably by farmers in California. The Chinese laborers were experienced farmers who were reportedly often better skilled orchardists than their employers (McWilliams 1935); they also tended to work in self-led teams, which relieved farmers of administrative and supervisory duties (DOL 1945).

However, while farmers might have seen various benefits, the Chinese farmworkers did not. By the late-1880s there was an organized campaign of anti-Chinese violence that continued through until the 1890s (DOL 1945). As a DOL (1945) report puts it, “a condition approximating civil war broke out in the great valleys of California,” which peaked in 1893 and 1894.

In the August of 1893, a mob drove off over 300 Chinese farmworkers from their work in fields outside of Fresno (DOL 1945). This initiated a series of anti-Chinese riots throughout the San Joaquin Valley centered in Fresno, Tulare, and Visalia (DOL 1945). Following these riots a “white laborer’s union” organized a mass meeting and protest aimed at ending Chinese labor in orchards within Napa Valley (DOL 1945). This preceded a series of raids and riots extending from Compton in the south to Ukiah in the north (DOL 1945; McWilliams 1935). These riots and raids continued throughout 1894 with major attacks in Anaheim, Vacaville, and Santa Rosa (DOL 1945).

In addition to discrimination based on race, immigrant status also contributes to the poor

treatment of farmworkers. The importance of immigration status in regard to the poor conditions encountered by the agricultural labor force can be seen in the experience of many contemporary farmworkers.

While the history of immigrant farm labor in the United States may be traced to Chinese farmworkers in the nineteenth century, since the Bracero Program most farmworkers within the country are now from Latin America (Gottlieb and Joshi 2010). Even though the Bracero Program ended in 1964, the reliance on immigrant labor from Mexico and South America has not. According to the US Department of Agriculture (USDA 2013), 71 % of all farmworkers are immigrants from Mexico and Central America, at least two-thirds of whom are undocumented (USDA 2013). Such undocumented status leads to mistreatment in a number of ways.

Many undocumented farmworkers are brought to the United States by human smugglers. As, the United States Department of State (DOS 2013) notes, those who are smuggled find themselves abused by their smugglers in a number of ways, including being misled about the locations to which they will be brought, the sort of employment that will be available, and being forced to work as a means of repaying the “debt” accrued during the emigration process. Many of the contractors that undocumented farmworkers are employed by are members of the same organized crime organizations that smuggle them into the United States (Gottlieb and Joshi 2010). And, these contractors often employ threats, violence, and – on occasion – murder to ensure compliance from their workers (Gottlieb and Joshi 2010).

Even if undocumented farmworkers are not subjected to abuse from human smugglers, their undocumented status still tends to undermine their welfare. Employers can use the threat of deportation to make it difficult, if not impossible, for workers to negotiate for better pay, benefits, or working conditions (Loo 2014). Being undocumented also prevents many farmworkers from notifying authorities when they are victims of crime or subjects of mistreatment (Loo 2014). It also prevents them from accessing protections and services such as minimum wage laws, child labor

laws, workplace safety regulations, health insurance, routine preventive medicine, and food assistance (Loo 2014).

With the above being the case, addressing farmworker rights unavoidably involves addressing disparities arising from racism and immigration policy.

Agricultural Labor Unionism

The other topic often discussed in the literature about farmworker rights is the organizing of farmworkers into unions. Two examples that are often referred to by scholars are the United Farm Workers (UFW) and the Coalition of Immokalee Workers (CIW).

The UFW formed in 1962 through the merger of the Agricultural Workers Organizing Committee and the National Farm Workers Association and soon after led a series of strikes and boycotts intended to improve (UFW 2016). Though these strikes and boycotts have had limited impact on the material conditions of farmworkers (Brown and Getz 2011), they have come to be representative of the farm labor movement. Indeed, several of the UFW’s campaigns, particularly the actions associated with the Delano grape strike, continue to be appealed to as examples that can inform strategy for contemporary efforts to improve conditions for farmworkers (Ganz 2009; Butovsky and Smith 2007).

Another commonly referred to case is the Coalition of the Immokalee Workers (CIW). The CIW formed in 1995 as a small group of farmworkers who met weekly to discuss the poor working conditions that they, and their fellows, were subjected to and to create a strategy to improve those conditions (CIW 2012a). In the following 20 years, it grew into one of the most influential worker-based farm labor advocacy groups in the world that has been recognized by the Clinton Global Initiative, Roosevelt Institute, Natural Resources Defense Council, US State Department, and Federal Bureau of Investigation.

More importantly, the CIW provides an example of how worker-led advocacy can serve as an effective means to address the mistreatment of

farmworkers (Brennan 2005). For example, the CIW's Fair Food Campaign, which involved employing farmworker-led advocacy to persuade a number of major retailers to sign agreements to improve wages for field laborers, is cited as a model for an effective strategy to promote farmworker rights (Alkon 2014). The CIW has similarly collaborated with major retailers – including Subway, Walmart, and Whole Foods – in their Fair Food Program to create a third-party monitoring group (the Fair Food Standards Council), to conduct worker-to-worker education regarding labor codes and standards, and to create a program where buyers pay a premium to ensure that farmworkers receive fair wages (CIW 2012a).

The CIW (2012b) has also worked with legislators and law enforcement through their Anti-Slavery Campaign to fight modern-day slavery within the US agricultural system (Brennan 2005). Through lobbying, training law enforcement to identify and assist those subjected to forced labor, and aiding in investigations, the CIW has contributed to the passage of the Trafficking Victims Protection Act of 2000 (CIW 2012b), the freeing of over 1200 slaves (Gottlieb and Joshi 2010), and nine separate convictions in slavery and human trafficking-related cases (CIW 2012b).

While working conditions are still likely inadequate, efforts by the CIW and similar organizations have in recent years increased the wages and have laid a foundation for a system of protections that might serve to protect farmworkers from exploitation by their employers.

Conclusion

To summarize, farmworkers encounter a host of adverse work conditions. These include but are not limited to poor pay, insecure work, food insecurity, workplace hazards, and abuse from employers. Those interested in farmworker rights seek to understand and work to improve these conditions through analysis of the responsible factors – often racism and immigration status – and examination of farm labor organizing to identify strategies that could be useful for shifting practices within the agricultural sector.

Farmworkers: Ethical Issues

Agriculture; Distributive justice; Farming; Labor; Slavery

Introduction

Farmworkers are among the most marginalized and underserved groups in the United States. While they make up a large and economically significant portion of the US population and workforce, and they provide a valuable and vitally necessary social service, they are chronically underpaid and underserved and are regularly exposed to serious risk of injury and sickness. This has been true for generations. This situation is the product of a complex set of immigration and

labor laws, economic interests, and deeply embedded attitudes about race and ethnicity.

This entry divides the ethical issues surrounding farmworkers into two categories: distributive justice and humanitarian crises. The first category, distributive justice, focuses on unfairness and inequity in the distribution of economic wealth, social influence, and political power to farmworkers. Poverty, access to social services, and political representation are of significant interest here. The second category, humanitarian crises, focuses on forms of harm and suffering among farmworkers that represent serious violations of rights that many scholars agree are fundamental, natural, or otherwise of particular importance.

The entry is organized into five sections, including this introduction. Section “[Background](#)” surveys some important statistics and empirical facts about the state of farmworkers in the United States and section “[Distributive Justice: Health, Housing, and Access](#)” discusses problems of distributive injustice, with particular attention paid to income, housing, and risk of injury and sickness. Section “[Humanitarian Issues: Child Labor in Agriculture](#)” explores the first of two humanitarian issues: the legality of child labor in agriculture in the United States and section “[Humanitarian Issues: Slavery in Agriculture](#)” discusses the second humanitarian issue: present-day slavery and forced labor practices in the United States. The scope of this entry is limited to ethical issues concerning farmworkers in the United States, though this should not be taken to imply that there are not significant ethical issues of philosophical interest in other countries and internationally.

Background

As of 2012, according to the USDA, approximately 787,000 farmworkers were employed in the United States – that is, approximately 0.5 % of the total US work force or one of every two hundred US workers (Hertz 2016). Other agencies and authors estimate that this number is significantly larger, perhaps up to three million individuals (Center for Disease Control 2014). Despite composing such a significant portion of the

workforce, farmworkers are subject to unique forms of discrimination and hardship – social, economic, and political.

Farmworkers are particularly economically disadvantaged in the United States. On average, farmworkers earn approximately \$10.80 per hour of work (Hertz 2016). While this has risen at approximately 0.8 % per year since 1990, that is insufficient to keep up with inflation. Annually, most farmworkers earn an average of \$20,000–\$29,000, which is below the poverty line for workers with children. For comparison, according to the US Census Bureau, the average US household earned approximately \$55,000 in 2012 (Noss 2016).

More than any other sector of the US economy, agriculture employs a particularly high percentage of unauthorized foreign workers. Since approximately 2000, roughly half of farmworkers in the United States are in the country without legal authorization to work. An additional 20 % of farmworkers are in the United States on temporary work visas. Only about 30 % of all US farmworkers are US citizens. The vast majority of farmworkers, approximately 70 %, are from Mexico (Hertz 2016).

One common misconception about farmworkers in the United States is that they are primarily migratory and have to “follow the crop” – that is, they move from region to region as the seasons change seeking work. In fact, approximately 75 % of US farmworkers are considered “settled” – they work within 75 miles of their home year round. Another 12 % work a single farm, but live over 75 miles away. Less than 5 % of farmworkers follow the crop.

It is important to note that while these are the USDA’s official statistics on farmworkers, facts about the nature of farm work today suggest that these numbers may not be a fair representation of reality. For instance, the USDA’s figures rely heavily on survey data and testimonial, but the stigma and harsh penalties associated with being an undocumented worker in the United States may make surveyed workers reluctant to participate honestly. Furthermore, the marginalized social position and poverty of workers may make them reluctant to complain about their working

conditions, fearful of reprisal, or losing their job. Thus some authors have estimated that, rather than 787,000, closer to three million people are employed as farmworkers and that significantly more are undocumented, migratory, and earn below the poverty line (Gottlieb and Joshi 2013, pp. 19–23).

Distributive Justice: Health, Housing, and Access

Farm work workers experience some of the harshest living and working conditions of any members of the US work force. The injustices of the US food system notably came to the public’s attention in 1960 as a product of the CBS documentary *Harvest of Shame*, presented by the respected newsman Edward R. Murrow. The program aired on Thanksgiving Day, and the juxtaposition of the bounteous holiday meal with the poor living and working conditions of the people who produced those meals shocked the conscience of the country. *Harvest of Shame* became a template for the exposé style documentary journalism that is widely used in the current food movement. It is worth noting that the attention of more recent productions has been on animal welfare and environmental harm, rather than the tragedy of human laborers.

Health issues are of particularly great concern for farmworkers. Two major health concerns for farmworkers are exposure to harmful chemicals at work and exposure to risk of serious bodily injury. Exposure to common agricultural chemicals, especially pesticides, at high levels has been linked to a variety of neurological, dermatological, and respiratory health issues (Kamel and Hoppin 2004; Beard et al. 2013, 2014). There is also evidence that moderate but regular exposure also has negative health effects (Kamel and Hoppin 2004). Reports of farmers being exposed in small and large doses, for instance, when they are doused with chemicals by crop dusters, have been released by groups like *Farmworker Justice*, which advocate for political changes for farmworkers. It is estimated that approximately 18 out of every 100,000 farmworkers, somewhere

between 180 and 540 individuals total, experience pesticide-related illness in the United States every year (Calvert et al. 2004).

Farmworkers are also exposed to serious risk of bodily harm and death during the operation of heavy machinery. According to the Center for Disease Control (CDC), 167 farmworkers suffer a lost-work-time injury every day, 5 % of which results in permanent impairment (Center for Disease Control 2014). In 2012, 374 farmers and farmworkers died from work-related injuries. Between 1992 and 2005, approximately 200 people died every year just from incidents involving tractors (Loring and Myers 2008). Within that same span of time, 113 young people under the age of 20 died every year from work-related injuries on farms.

Housing is also a major concern for farmworkers. According to Gottlieb and Joshi,

Where farmworkers are housed has also become part of the system of abuse and unhealthy living conditions. When employers have provided housing for farmworkers, the conditions have at times been scandalous, including barbed wire encampments and even five-by-five caves that the workers had to dig themselves, as a California Rural Legal Assistance Lawyer documented. There continue to be problems of enormous overcrowding, leading to farmworkers' suffering from poor sanitation and proximity to pesticides. . . . A California Agricultural Workers Health Survey (CAWHS) found that nearly half of the housing of California farmworkers was overcrowded (Gottlieb and Joshi 2013, p. 21).

Despite these challenges, many farmworkers and farmworkers' households do not avail themselves of the social programs designed to support economically marginalized communities in the United States. A recent study found that only 12 % of eligible *documented* farmworkers' households and 10 % of eligible *undocumented* farmworkers' households were enrolled in the Women, Infants, and Children (WIC) federal supplemental nutrition program (Leigh and Medel-Herrero 2015). Obstacles to enrollment include lack of knowledge, fear of deportation, lack of a permanent address, and uncertainty of eligibility.

Perhaps the foremost advocate for the equal rights and opportunities of farmworkers in the United States is the United Farmworkers

Organizing Committee (UFW). The heir to the National Farmworkers Association (NFWA), founded by Cesar Chavez and Dolores Huerta in the mid-1960s, the UFW works to create better conditions for farmworkers through unionization, collective bargaining, and collective action (UFW 2016).

Setting aside more fundamental issues concerning the moral significance of human suffering and indignity – which will be addressed at length in the next sections – the living conditions of farmworkers in the United States raise questions about distributive justice. Primary among these questions is whether farmworkers have a right to better living conditions or to the resources sufficient to create such conditions. One particularly potent argument *against* such a right flows from the libertarian perspective most frequently associated with Robert Nozick (1975). Drawing on arguments and ideas attributed to John Locke, the libertarian argument presses that although farmworkers may endure significantly worse working and living conditions than other people, they consented to those working conditions when they took their jobs (Locke 1980). Because they agreed to the terms of their employ, they do not have the standing to demand more either from their employers or from society at large in the form of additional social services or protections. Opponents to such arguments might contest the premise that all or most prospective workers *do* consent to such harsh labor and living conditions, citing deceptive hiring practices, language barriers, and economic desperation as factors that undercut genuine consent.

On the other hand, certain egalitarian or quasi-egalitarian theorists, especially those sympathetic to the work of John Rawls, would likely argue that farmworkers are entitled to improved living conditions, for instance, by means of increased minimum wages or additional social services that more fairly redistribute a society's wealth (Rawls 2005). Philosophers with egalitarian leanings might, following Rawls and Hart, adopt a version of the fair play argument to argue that because farmworkers contribute as members to the well functioning of our society, they are entitled to a fair share of the benefits of that cooperative

venture (Hart 1955). More specifically, because farmworkers play an essential role in the production of food, an essential social good, they are entitled at least to the share of wealth and access to social services available to that society that are necessary for a dignified life. Even granting that fair play arguments identify genuine political obligations, opponents might respond that such arguments, as envisioned by Rawls and Hart, ground entitlements only for members of a system of social cooperation (like neighbors in a homeowners association, as envisioned by Nozick in his radio station example) (Nozick 1975). Farmworkers per se, the argument goes, are not members of a system of social cooperation that includes agents, agencies, or institutions capable of raising a minimum wage or ensuring social programs. This is especially true of illegal, undocumented, and noncitizen workers. The argument concludes that farmworkers, especially undocumented workers, have no such entitlements.

Humanitarian Issues: Child Labor in Agriculture

Beyond issues of distributive justice, some moral questions raised by the circumstances of farmworkers in the United States could be categorized as genuine humanitarian crises. These problems are not merely examples of unfair or even discriminatory policy but are violations of what many consider to be fundamental values or basic human rights. As mentioned earlier, exposure to unnecessary and elevated risk of illness, bodily injury, and violent premature death might belong in this category. We will now address two other, starker, examples: the legality of child labor and the persistence of modern day slavery in the US agriculture industry.

According to the Fair Labor Standards Act (FLSA), and unlike any other industry in the United States, children of any age may be employed on a farm – and they are (US Department of Labor 2007). Under the age of 12, children can only be employed with parental consent and outside of school hours. At age 14, no parental

consent is necessary so long as the child is not filling an occupation declared hazardous. At age 16, children may perform hazardous occupations and need not be employed outside school hours. Parents who employ their own children are exempted from even these rules, such that “A child of any age may be employed by his or her parent or person standing in place of the parent at any time in any occupation on a farm owned or operated by that parent” (US Department of Labor 2007). The most recent data from the National Agriculture Workers Survey (NAWS) estimates that 126,000 children are employed as paid farmworkers (National Agricultural Workers Survey 2000). The Government Accountability Office (GAO) estimates that the number is closer to 155,000 children (Gottlieb and Joshi 2013, p. 20).

Children working in agriculture are exposed to greater risks than their adult colleagues. One study, specifically on how changing labor laws in agriculture might affect the well-being of children, found the following:

- Nearly half of all fatal occupational injuries among children occur in agriculture.
- Children are three to four times more likely to be fatally injured in agriculture than in other occupations.
- Seventy-six percent of fatally wounded children were working on their parents’ farm (Marlenga et al. 2007).

The clear majority of cases wherein children are injured or fatally injured working on a farm appear to involve tractors and other farm machinery (Marlenga et al. 2007, p. 280). Children can also be harmed by the crop with which they work itself. This is particularly apparent among children who work on tobacco farms, who report skin, eye, respiratory, and musculoskeletal problems connected to constant exposure to tobacco resin (which contains nicotine) (Gamlin 2011). Authors speculate that the reasons for these increased risks are connected both to the intrinsic physicality of farm work and the fact that some parents and children are unaware of the risks (Hurst 2007; Gamlin 2011).

Child labor in agriculture poses a variety of questions for moral philosophers, but we will investigate only two here. First, should parents have the legal authority to allow their children to work on farms? One might be inclined to argue that, as their primary caregivers, parents and legal guardians are in a position to know what is best for their child, and so should have this authority. One might even go so far as to say that parents have a natural right to decide what their children may or may not do and that it would be an intrusion into their family's private life for any entity – even and especially the government – to command otherwise. Indeed, the sanctity of family privacy and respect for a parent's dominion over their child appear to be the primary values grounding existing law. But one might object that granting parents this legal authority exposes children to forms of parental exploitation and poor judgment. Parents, especially in conditions of financial need and absent any meaningful understanding of the potential for harm, might comprehensibly choose to risk their child's well-being for the good of the family by asking them to work. But just as parents may not and should not be allowed to play Russian roulette with their children, the objection goes, so they should not be allowed to send their children to work on a farm.

A second, and perhaps derivative, question moral philosophers might ask about child labor in agriculture is whether agriculture's special exemption from the more stringent child labor laws that govern other industries is justified. Historically, the exemption for agriculture was grounded in a deep agrarian belief that "farm labor for a child was a divine occupation, strengthening the moral constitution of the child" (Curtiss 1995, p. 308). This belief was only reinforced, and the dangers of agricultural work overshadowed, by the conditions of workers in American factories and mills. But given the known hazards of farm work – from machinery accidents to chemical and sun exposure – it is not obvious that the agrarian vision is borne out. A possible alternative justification might be that the realities of childrearing in an agricultural context necessitate allowances for the presence of

children. Further philosophical inquiry is required to fully parse this question.

Humanitarian Issues: Slavery in Agriculture

Another particularly bleak and patently problematic reality of farm work in the United States is its historical reliance on and current continuation of slavery and forced labor. Many or most consumers in the United States are unaware that slavery persists in the world, not to mention in their country. Nevertheless, stories workers being exploited, abused, and forced to work in undignified conditions surface regularly. Here are two examples from recent scholarship:

In 2004, the owners of a tree-cutting business in New Hampshire hired workers from Jamaica under the H-2A guest-worker visa program. The workers were recruited in Mexico with promises of good wages and housing accommodations. When the workers arrived, they discovered that they were paid half of what they were promised, and would have to pay \$50 per week to live in a dilapidated trailer with no electricity or running water. The employers confiscated the workers' passports and warned them about a worker who had run away. (Hager 2010, pp. 173–174).

On November 20, 2007, three men described to Collier County sheriffs their chilling escape from a tomato-harvesting slavery ring based in Immokalee, Florida. . . . The workers had punched and kicked their way out of a padlocked 28-foot-long box truck two days earlier. . . . The workers had at times been locked and chained inside the truck, forced to urinate and defecate in its corners, and charged five dollars apiece to bathe outdoors with a garden hose. Held against their will, they received vicious beatings when they were unable or unwilling to work or when they attempted to flee. The enslaved crew harvested some of the nation's largest tomato farms. (Sellers and Asbed 2011, pp. 29–30).

The Florida tomato industry has in fact been at the center of concerns about slavery in modern agriculture. Indeed, the persistence of labor abuses among Florida tomato growers led to the formation of the Coalition of Imokalee Workers (CIW) in 1993. A group of Latino, Mayan Indian, and Haitian workers, the CIW has become a national organization at the forefront of the

political and legal fight against modern agricultural slavery whose “campaigns have focused on the role of the huge food industry players and fast food companies in influencing the wages, working conditions, and abuses experienced by farmworkers” (Gottlieb and Joshi 2013, p. 17).

Although scholars will hopefully agree that abuses like those described above represent moral wrongs, they will likely disagree about what precisely is so wrong with them. Consequentialist philosophers, for instance, might argue that slavery and forced labor are wrong precisely because of the avoidable suffering they produce – at least in the absence of sufficiently great utility being produced thereby. Other authors – Fredrick Douglass is notable among them (Douglass 1995) – might argue that modern slavery is wrong because it violates natural human rights. Certainly, Douglass’s view resonates with modern antislavery documents, specifically including Article 4 of the Universal Declaration of Human Rights (“The Universal Declaration of Human Rights” 2014). Others, whose work strongly emphasizes the power of persons to relinquish their rights by an act of will, might argue that while people may agree to work in undignified conditions like those described above, it is wrong to *force* a person to do so (Nozick 1975).

The case of modern slavery in US agriculture should be of particular interest to moral and political philosophers precisely because of the fact that so many different theories of right will produce congruent judgments about it. Much of moral philosophy has concerned itself with complex thought experiments at the margins of experience, since these extreme and often highly fictionalized cases highlight where theories of right depart from one another. By focusing on where philosophies diverge, we gain insight into what is at stake when we commit ourselves to one or another view. Slavery in US agriculture is likely not a place where philosophies diverge but is a special case of widespread overlap in judgments. It raises the question whether moral theory has any role to play, besides revisiting the issue for the sake of quality control, once an overwhelming judgment has been passed.

Conclusion

Farmworkers are subject to extreme and morally salient perils, even as they provide the basic means for survival and flourishing of other members of their societies. Poverty, discrimination, and physical danger are parts of their daily experiences, and this should be deeply concerning to scholars, consumers, and political leaders alike.

[Penitence](#); [Purgation](#)

Introduction

Voluntary fasting as opposed to inedia induced by psychological disorder or famine poses a number of ethical quandaries. First, since eating is a biological prerequisite for life, it would appear contrary to the dictates of survival that fasting could be used to promote health. Yet from a purely evolutionary vantage point, as gatherers and hunters, our bodies have adapted to an unpredictable food supply and even flourish without regularly scheduled meals, which are the product of a sedentary lifestyle and comparatively dependable food supply, fairly recent in the history of our species. Moreover, in the past ten millennia, the possibility of overeating has given fasting a purgative function for those able to overindulge. Several days without food has been considered physically cleansing, but obviously, there is a limit to the extent humans can go without food before wasting away and dying.

Fasting Through History

In addition, fasting has been thought to provide a form of spiritual refreshment by shedding excess corpulence, denigrating the body, and thereby strengthening the soul. In many religious traditions, fasting is an act of penitence, a form of contrition, intended to punish the body and impress upon supernatural beings the earnestness of human endeavors and willingness to reform. Both the individual occasional fast and the communally prescribed fast held on regular holy days or emergent situations such as impending disaster, war, disease, or even, oddly enough, famine were believed to communicate directly to God and appease his wrath. That is, assuming such calamities were sent as a form of punishment, the fast thus becomes a means of regaining favor.

Likewise, for the disempowered, fasting has been a means of exerting the human will when no other recourse is possible. The slave who refuses food and prefers death to submission, the prisoner who fasts as a form of political protest, and, even on a less ostensibly intentional level, the anorexic whose life is completely at the mercy of superiors has one last means of empowerment in controlling food intake, often to pathological extremes. Whether for health, spirituality, or gaining power over oppressors, fasting is nonetheless a potentially dangerous practice, and despite heroic feats of going without food attributed to holy figures and medical marvels, the human body is gradually destroyed without suitable sustenance.

This entry will recount numerous examples of fasting drawn from history and the present, to provide both a taxonomy of the practice and an inquiry into the ethical ramifications of going without food, how it impinges on our existence as individuals, and the many benefits it has been thought to confer.

In the Jewish tradition, there are two principle types of fast although both are intended to be a means of communicating with God contrition and atonement. The book of Leviticus (XXIII, 26–32; XVI, 29–31) specifies that on the seventh month on the tenth day “ye shall inflict your souls” meaning no work can be done and no food eaten. The intention is to cleanse the soul by

meditating on one’s sins and separating from them. This holy day, which extends from sundown to sundown, called Yom Kippur, is still practiced even by many completely secular-minded Jews. There are several other fasts, usually observed strictly only by Orthodox Jews: Tisha B’Av commemorates the destruction of the First (586 BC) and Second Temple (70 AD) as well as the expulsion from Spain (1492) and the Holocaust, as well as other calamities. There are also lesser fasts such as the Fast of Esther before Purim, the fast of the first born before Passover, and a few others (Cooper 1993).

There are also voluntary individual fasts in the Jewish tradition, such as when Moses fasted 40 days and nights, when Joel tried to avert God’s wrath, or when David repented for his adulterous relationship with Bathsheba. Similar acts of repentance were performed by Jesus and his disciples and the question of whether fasts should be regularly scheduled, should consist of complete abstinence from food or only from certain foods and for certain hours, remained a major question throughout the history of Christianity. In biblical Judaism, there were also public fasts for emergencies, when invading armies threatened or some other impending disaster.

The larger question though is why would abstinence from food please God? Why would intentional suffering constitute a meritorious act – in Hebrew a *mitzvah*? Eating is certainly pleasant and a distraction from more serious matters. But more importantly, fasting is a sign of remorse, to show seriousness of purpose and true contrition. Going through the formal motion, the empty ritual itself, is to no avail, and in fact biblical fasting would have been accompanied by weeping, beating the chest, tearing one’s clothes, and strewing ashes on one’s head. Most importantly, the act of fasting is meaningless unless accompanied by a true intention to improve one’s ways. This is why Isaiah recommended fasting in private, so as not to draw attention or praise from others.

The Hindu tradition also embraces many fasts, and devotees to a particular God often fast on a certain day: followers of Shiva on Mondays and Vishnu on Thursdays. Festivals such as Maha Shivratri (Shiva’s Day) or the week before Diwali

are also fast days. Other fasts are performed in specific localities in honor of various deities and may entail complete abstinence from food or of meat only. These are considered *vrata*, an obligation or promise intended to gain blessings and favor with the Gods. The word *vrata* is cognate with vow, and thus it is a kind of stated agreement between the individual and deity to perform certain actions such as fasting, in return for benefits.

Asceticism, including fasting, is also a major current in Hindu worship, accompanied by meditation, yogic practice, and sometimes bodily mortification. These are intended as means to spiritual purification, renouncing worldly pleasures to attain wisdom. Jains also practice asceticism, along with nonviolence, giving up possessions, and other austerities including celibacy for monks. It was this tradition of asceticism that Siddhartha Gautama tried after leaving home in his search for wisdom but eventually rejected in favor of the “middle way” by which one neither longs for pleasures nor seeks merit in extreme self-denial – but rather detaches from such matters as essentially unimportant and eating merely to live. The Theravada Buddhist traditions follow this middle way, whereas the Mahayana of China and Japan, monks are usually vegetarian. Many Buddhist monks do not eat a meal in the evening, though this is primarily for health reasons and not considered a proper fast. These interdenominational or confessional disagreements over fasting are common in most religious traditions.

As Christianity began to define itself as separate from Judaism, the question of fasting was seriously considered by authors such as Tertullian and Basil. While it was clear that the kosher laws of the Old Testament had been abrogated and there were occasions when Jesus and his disciples consciously ignored Jewish custom, they did fast for emergent occasions. Jesus, like Moses, fasted 40 days and nights in the desert. His disciples did likewise to atone for sins. Early Christianity also embraced asceticism which stressed physical denial as a path to spiritual strength. But these were acts of holy men and sometimes women, certainly not possible for ordinary people. Gradually the church instituted regular days of fasting, every Saturday, starting on sundown Friday night;

the vigils of saints’ days; the so-called *quatuor tempori* or Ember Days; and most importantly Lent, the 40 days between Ash Wednesday and Easter minus Sundays. The evening before particular saint’s days might be set aside for fasting, in some places, Wednesdays as well. There was wide divergence in practice (Henisch 1976).

These fasts did not involve total abstinence from food, merely one meal a day before sundown and sometimes smaller collations or snacks in the morning or evening, but no meat or meat products were allowed. The original logic was primarily medical: meat was categorized as hot and moist and very nutritious. It increases the libido and therefore inclines one to sin (Shaw 1998). Contrariwise, fish and vegetables are cold and aid in sexual abstinence. Many monastic orders inclined toward vegetarianism for these reasons, though in the course of the Middle Ages, this position became suspect as heresy. The Albigensians had declared all matter sinful and refused to eat meat and eventually all food, some adherents starving themselves to death. This was obviously considered a sin, but so too was permanent avoidance of flesh since the New Testament says in many places that all food is good.

Fasting regulations applied to all people with exceptions for illness, pregnancy, and age, but individuals and sometimes whole towns could purchase exemptions allowing them to consume some meat products, perhaps butter, or even meat on fast days. By the sixteenth century, there was perceived to be widespread abuse of these regulations. Moreover by turning to the scripture as a higher authority over tradition, many Protestant reformers found no biblical warrant for regularly scheduled fasts. For Martin Luther, private individual fasts were fine, since they are found throughout the Bible, but not the complex regulations that had arisen since. In the Reformed tradition, public fasts were imposed, exactly as in the Old Testament, to avert God’s wrath during war and epidemics. Although most Protestant churches abandoned regular fasts, the Calvinist churches, along with public fasts, introduced a kind of year-round austerity in food and mode of living as an ideal. The Catholic Church retained earlier fasting practices and they stood in place,

with traditions such as fish on Fridays, until the 1960s when the restrictions were loosened. Yet many Catholics still give up meat during Lent and on Friday nights.

Fasting in the Eastern Orthodox Churches is rather more rigorous, though it still involves giving up meat and meat products as well as oil and for some fasts fish as well and alcohol. There are also many more days through the calendar still observed as fasts, not only Lent but holy days throughout the calendar and normally any day at sundown the day before one intends to receive communion. The Pentecostal Church and the Mormons also have regularly scheduled fast days.

Muslims also fast, during the entire month of Ramadan, taking no food or drink from sunrise to sundown. It is considered one of the pillars of Islam, along with charity. The practice is intended to bring the faithful closer to Allah, through purification of both mind and body, since no negative thoughts or words are to be expressed either. A sumptuous meal often closes the observance in the evening.

Fasting for religious purposes in all cases assumes a certain relationship to God which can be improved. The Gods must be appeased, or in a certain sense convinced of sincerity and contrition before one can be absolved of sins. In most cases, the body is seen as a distraction hindering the full development of the spirit, which grows stronger through self-denial. Secular fasts are entirely different, though the motivation may be similar. Fasting is essentially a means of empowerment. Asserting control over the body gives one a sense of accomplishment and purpose and the ability to make negative situations better. Thus both religious and secular fasting may spring from similar psychological urges common to all people.

As Nietzsche described it, in the face of strong and powerful people whose values are strength and beauty, as well as eating meat in heroic portions, the weak and oppressed use abstinence as a kind of secret ethical weapon. The reward for such righteousness comes in the afterlife, in salvation. But Nietzsche saw it springing from a kind of spite directed at the powerful. Building on these ideas, Freud postulated that ordering and controlling the body is a substitution for not being

able to act on our libidinal urges, so it makes perfect sense that the holiest of people, who deny themselves the most, would also be the most rigorous in self-chastisement, the ascetic in the past and the present. Both thinkers see fasting as a form of empowerment, but it is only one that could have been devised by the disenfranchised.

The empowering nature of fasting might even be true of the purgative fast intended only for improving health. A sense of bodily pollution, whether it be excess fat or a feeling of having consumed too many intoxicating substances, is a feeling of inadequacy that originates in the mind. It may be strongly influenced by cultural signals such as advertisements for weight loss or images of ideal bodies. At root this is similar to the sense of guilt and shame arising from ethical failings. The body thus needs to be purged of sin – whether this is a sense of moral failing stemming from wrongdoings or from having consumed the “wrong” foods and drinks. The fast in both cases washes sins away, with divine intervention in one case and through scientific or quasi-scientific means in the other. The goal is the same, righteousness, happiness, and social approval.

There are several different varieties of therapeutic fasting, though they overlap in many respects. For example, an individual may undertake a voluntary weight loss fast, but a similar kind of fast or drastic reduction in food and abstinence from certain types of food might be prescribed by a physician. There are also fasts as part of standard regimens, before anesthesia or before testing for cholesterol levels. But these should be kept distinct from the fast which purports in and of itself to maintain health or affect cures. Such therapeutic fasts are nothing new, and even in ancient medicine, Hippocrates and Galen prescribed them for certain ailments. The former contended that people have a “physician within” or a certain internal force that heals when the body is not taxed by digesting food. Popular weight loss fasting regimens began to proliferate in the eighteenth century, the most renowned devised by George Cheyne, though it was mixed directly with a kind of religious purification as well (Guerini 2000). The secular fast as a form of therapy ran through medical thought for centuries,

but fasting was not usually recommended for those in good health.

This changed in the late nineteenth century when the modern fasting fad spread in the wake of Dr. Henry S. Tanner's remarkable feat of going without food for 40 days. Physicians were present to monitor his health throughout the fast. It was staged at Clarendon Hall in New York City in 1880, and though he did lose about a pound a day, he came out of the experiment otherwise in good health. Edward Hooker Dewey thereafter published several books on the *Fasting Cure* and *No Breakfast Plan*. In these he described his experience curing people of ailments as diverse as melancholia, obesity, insanity, and chronic alcoholism. This was the era of rampant diet fads and health cures, the most famous advocated by John Harvey Kellogg. But fasting per se had its own enthusiastic adherents. Bernarr Macfadden, the body building guru, pushed fasting in his popular book *Fasting for Health* published in 1923. It was meant not as a curative but a general practice for all people. Herbert M. Shelton was probably the best-known advocate of "Natural Hygiene" in the twentieth century, and his book *The Science and Art of Fasting* was very popular, despite his being arrested many times for practicing medicine without a license. Although the motivations and goals of these figures may have differed, they all brought the idea of fasting in the popular imagination, as part of alternative medicine, dieting, and body building, and it remains a legacy of these people today. There are also many mainstream physicians today researching the effects of reduced calorie diets on longevity and the role that periodic fasting may play in maintaining health.

Another species of fasting which can also be therapeutic is the fast intended to aid in harnessing supernatural forces. Fasting is a part of most traditions of magic, here defined as an individual's ability by means of spells, amulets, incantations, and rituals to make use of occult powers to achieve specific tangible ends. That is, a purification ritual involving fasting usually precedes the magic ritual. Whether the individual starts hallucinating after prolonged abstinence, really believes he or she is controlling supernatural powers, or is a simple charlatan is irrelevant. Going

without food is often believed to make that connection to unseen forces possible. This might be the alchemist seeking spiritual perfection, the shaman contacting spirits to cure a sickness, or a magus in any tradition.

The serious ethical dilemmas posed by fasting naturally grow with the extended duration of the fast. A day or two without food, or even several weeks without meat, will not destroy the body, but over a week without food and especially without water can have permanently damaging consequences including death. Whether any goal can justify self-destruction cannot be answered here, though many individuals who have fasted as a form of protest have gained popular sympathy.

The most renowned example of a hunger strike was Bobby Sands, a Northern Irish activist working for the IRA who was imprisoned in the 1970s. From prison he wrote poetry and opinion articles and was even elected to Parliament. In 1981 he went on a hunger strike essentially demanding that prisoners such as himself be treated as political prisoners of war rather than common criminals. After 66 days without food, he died, gaining wide publicity and sympathy for the movement. Nine other hunger strikers followed to their deaths. These events raised many questions. They certainly increased awareness of the war in Northern Ireland, and recruits to the IRA increased in the following years, ultimately escalating violence. To some Sands was a hero fighting for freedom, to others a terrorist directly supporting the killing of innocent people.

From an ethical standpoint, the famous hunger strikes of Mahatma Gandhi against British rule of India, which took place from the 1920s to 1940s, were much more straightforward. As a revered public figure, the British were anxious not to let Gandhi die in prison and gain greater support. More importantly, these were calls to acts of non-violent resistance and they of course ultimately achieved their goal of independence.

There have been many examples of hunger strikes among political prisoners since the 1980s, most recently among Palestinian prisoners in Israeli jails. The real ethical question is not whether damaging or killing yourself for a larger cause is justified, but whether a person fasting can

be force-fed to save their life. A physician's duty is simply to save lives regardless of contingent circumstances, and while the World Medical Association has declared force-feeding degrading and inhumane, a physician may still follow his or her own conscience in saving a dying person. The negative stigma associated with force-feeding stretches back to the era of the women's suffrage movement when imprisoned women would be tied down and force-fed and even further back to African slaves who would be shackled and have food crammed through a funnel to prevent them from starving themselves. The question still remains though, is it ethical to fast to the point of death, to avoid enslavement, to gain rights, or as a form of political protest against oppression?

Similar ethical issues are raised by cases of miraculous fasting. There were several celebrated young women in the middle ages and early modern era who went for remarkable lengths of time without eating (Bell 1985). Some historians consider these cases of anorexia nervosa, though they might also be considered hunger artists, since they sometimes seemed to thrive on attention and notoriety. In either case, the root cause is similar to other fasts as well as to anorexia in general; they are an attempt to become empowered for those who feel out of control or helpless. In the medieval examples such as Lidwina of Schiedam who suffered a terrible skating accident, lost her appetite, and eventually gave up eating altogether for many years, the fasting was considered miraculous and she was later made a saint.

In later examples, observers seem to have been more skeptical, though physicians did often vouch for the truth of some amazing claims. Catharina Binder of Schmidweiler in Germany was still venerated in the 1580s, but in later examples, increasingly physicians sought natural causes or simply dismissed these cases as fraud. There was a celebrated case of one Barbara Kremer that was exposed as a sham in a book by Johannes Weir in the late sixteenth century. There were French cases, Jeanne Balam, and English ones, Martha Taylor, in the 1660s, and increasingly, scientific verification or explanation was sought. By the early nineteenth century, the celebrated fasting girl Anne Moore was uncovered as a fake. In these examples, it is

clear that the typology of a "fasting girl" became so familiar that many young women could pretend, presumably as a way to get attention.

In the late nineteenth century, there was a further string of renowned fasting girls; the most infamous was that of the young Welsh girl Sarah Jacob, whose parents allowed her to be supervised in a hospital to verify the claim that she did not eat at all. Despite signs of starvation, her parents insisted they keep watching and the girl eventually died. The parents were sent to prison for manslaughter (Jacobs-Brumberg 2000). There is no doubt that many of these cases were simply anorexia and that, rather than intentional deceit, the young women were merely exploited by others for fame and profit.

Profit is also very clearly the motive for the so-called hunger artist, and by the late nineteenth century, this was a recognized genre of performance with many well-known stars such as Giovanni Succi. The short story by Franz Kafka published in 1922 recounts an artist who fasts for entertainment in a cage, who despite his popularity is forced to stop after 40 days. Later he gets a job at a circus where he can break his own record, but no one is interested any more, and he eventually dies. Whatever the meaning of the story, it does coincide with the lack of interest in fasting as performance art in the modern era. On the other hand, magician and endurance artist David Blaine did fast for 44 days suspended in a plexiglass box near the Thames in 2003. Despite heckling, Blaine emerged as a hero, providing an example of human endurance, but one wonders what else?

In all cases mentioned, the great paradox of fasting is that the goal is to gain power, notoriety, and sanctity. By denying a fundamental physical requirement, which scientifically is known to be dangerous if prolonged, somehow people are thought to become stronger, more just, cleaner, or simply in greater control.

Summary

Throughout history and in many religious and secular contexts, fasting is a phenomenon which is believed to empower people either through divine

intervention or by gaining control over the body. Fasting has also been used therapeutically for promoting health and longevity, which is ironic since especially in excess, fasting causes direct physical harm. Fasting can also be used as a tool of political protest and as entertainment in the case of hunger artists. Miraculous fasts may be seen either as a form of anorexia or as closely related to religious fasts.

Introduction

Starting as early as conception, parents are intimately responsible for the feeding of infants, ensuring their sustenance, survival, and ability to thrive. Due to the biological phenomena of pregnancy and breastfeeding, mothers often hold the initial responsibility for feeding infants and continue to provide, purchase, prepare, and serve food for their children. Fathers are also involved to a degree that varies by culture and even from family to family. As babies grow into toddlers, children, and adolescents, parents continue to exert control and demonstrate care in child-feeding practices. Children also express their own food preferences, which change over time

and are greatly shaped by parental role modeling and parenting style. Particularly as childhood obesity rates have increased in many countries across the globe, questions of how and what to feed children have garnered heightened attention.

Starting with a short history of philosophical approaches to feeding children, this entry then employs studies and examples from the United States, Canada, and the United Kingdom to explore a variety of factors that currently influence the feeding of children, particularly in the modern West. The entry begins by examining the role of parents, starting with the politics of breastfeeding and then outlining the influence of role modeling, parenting style, and sources of parental motivation. The entry then turns to children themselves, examining the agency and decision making of children to influence family food decisions and to feed themselves. Child-centric food marketing, children and supermarket shopping, and the evolution of children's cuisine and menus are each discussed as case studies that embody the ethics of feeding children.

Philosophical Approaches to Feeding Children

While philosophers have more rarely discussed feeding children, they have discussed feeding infants at length. For example, writing near 350 B.C., Aristotle covers in great detail the nourishment of children in the womb via the mother's blood. As Bergès (2013) discusses, Aristotle strongly promoted breastfeeding in Book VII of the *Politics* to the extent of legislating adequate maternal diets and breastfeeding adherence. In his history of breastfeeding, Short (1992) not only emphasizes Aristotle's breastfeeding promotion, but also reveals Pliny, Plutarch, and Tacitus' opposition to wet nursing, as they argued it decreased the bonding between mother and child that breastfeeding naturally facilitates.

Similarly, Jean-Jacques Rousseau, whose eighteenth-century philosophies informed the French Revolution, strongly promoted breastfeeding, arguing that it naturally awakens and instills morality in children. Mary Wollstonecraft,

an eighteenth-century British philosopher, also supported requiring women to breastfeed, believing not only that the care of children was a woman's duty, but also that the contraceptive properties of breastfeeding benefited women (Bergès 2013). Bergès also discusses how in more recent years philosophers have debated if women should be required by law to breastfeed, discussing the balance between an infant's right to nutritional sustenance through breast milk and a woman's right to choose how she uses her body.

Throughout the history of civilization, philosophers have acknowledged the role of women in feeding infants and children. While Aristotle argued that women feel greater concern to feed children than men – rooted in either gender-specific compassion or the fact that mothers tend to spend more time with their children than fathers do (Mayhew 2004) – a woman's role in feeding children is even more complicated in contemporary societies. Nel Nodding's work around the ethics of care also provides an example of contemporary thinking on gender, ethics, and moral actions (Smith 2004), which could be applied to the feeding of children. In such a way, parents feeding children can be understood as an expression of care that according to Nodding is basic to human life and thus requires no ethical effort, particularly in women's experiences (Smith 2004).

The Role of Parents in Feeding Children

As food providers, role models, and guides, parents powerfully influence the taste preferences, eating behavior, food views, health, and weight of their children. While most humans exhibit early on a genetically determined predisposition to prefer sweet and salty flavors and to dislike bitter and sour ones, these preferences are also modified by life experience and environmental context. It can be argued that the feeding of children begins in the womb, as a mother's dietary choices during pregnancy shape not only a child's health, but may also influence taste preferences. Once a child is born, feeding continues by means of breastfeeding or bottle-feeding. As Van Esterik

(2013) shows, women have throughout history had choices when it comes to feeding infants. Her work demonstrates, however, that in present day societies, political, economic, and cultural issues surround breastfeeding, revealing the intersecting, and at times competing, interests of parents, children, governments, health professionals, and the infant formula industry. For example, while significant research has proven the health benefits of breastfeeding for both mother and child, breastfeeding is not always a feasible option for working mothers. Furthermore, based upon cultural views and societal standards, breastfeeding a child, particularly in public, can be viewed by some as maternal and natural and by others as taboo behavior. Especially in countries like the United States where breasts are highly sexualized, particularly in the media, breastfeeding can elicit conflicting perceptions of cultural appropriateness, which mothers must navigate. These are but a few examples of the myriad factors that influence a mother's choice to breastfeed or bottle-feed her child.

As children grow, begin to eat solid foods, and are weaned, they observe, and to a certain extent absorb, the eating practices of parents and caregivers. Whether they frequently eat and enjoy high-calorie foods or diet in order to maintain or lose weight, parental eating behavior may influence both the eating habits and perceptions of their children. Most generally, however, children eat differently than adults. From early on, children tend to prefer familiar foods. A certain amount of *neophobia* (the tendency to reject new foods) is common among children, particularly between 18 and 24 months of age. As Benton (2004) discusses, this phenomenon appears to be relatively consistent across cultures, as it is of arguably evolutionary importance, protecting newly walking children from potentially poisonous foodstuffs. While neophobia can be worrisome and frustrating for modern day parents, it is possible to guide children in their exposure to new foods. For example, repeatedly exposing a child to an initially disliked food can overcome resistance. While each child is different, studies show that children refuse a new food a median of 11 times (Benton 2004). Forcing a child to eat a food,

however, will only increase dislike for that food. In addition, restricting access to certain foods, such as junk foods, increases rather than decreases a child's desire and preference for these foods (Benton 2004).

Beyond role modeling and guiding, parenting style also greatly affects child feeding (Hubbs-Tait et al. 2008). While there are multiple theories and a variety of categories demarcating parenting styles, studies that explore the influence of parenting style on child-feeding practices typically employ the following categories: authoritative (high control and high warmth), authoritarian (high control and low warmth), and permissive (low control and low or high warmth). The research of Hubbs-Tait et al. (2008) confirmed that these general parenting styles correlate with feeding practices. Generally, authors found that authoritative parents encourage a child to eat a healthy diet while also considering a child's taste preferences. Authoritarian parents attempt to control a child's food intake with little consideration for the child's preferences, often restricting specific foods. Permissive parents allow the child to control what, where, and how much he or she eats, a style that can be characterized as either more indulgent or more neglectful compared to other styles. Trends in parenting styles reveal a shift away from restrictive parenting, privileging a more permissive approach. Notably in a contemporary context, both permissive and authoritative parenting styles appear to grant requests for food (O'Dougherty et al. 2006).

Parenting style and child-feeding practices greatly shape what and how a child eats, particularly when certain foods are restricted or promoted. Parents may restrict foods considered unhealthy, such as fast food or sweets, in order to nurture a child and ensure his or her health and safety. This restriction, however, can cause a child to more strongly desire these forbidden foods. In addition, parents who are concerned by a child's weight status may limit a child's access to food in an effort to help the child lose weight. Current evidence reveals, however, that such a strategy may prevent a child from learning to regulate his or her own intake, thus causing longer-term harm (Benton 2004). Conversely, parents may also use

food as a reward, which reinforces taste preferences for sweet and fatty foods. Parents may also use specific foods as a form of punishment, which can further reinforce dislike for particular foods, such as vegetables.

Whether promoting broccoli or restricting candy, a variety of factors motivate parents when feeding children. In their study of the mother plus child “new super consumer,” Coffey et al. (2006) posit that mothers are stimulated by a combination of four major motivators. First, mothers desire a positive self-image, aspiring to be good mothers. Second, they must balance the needs for convenience and time management, feeding children alongside other daily duties. Third, mothers desire and feel responsible for nurturing their children and keeping them safe. And, finally, mothers want to make their children happy.

Children, Agency, and Food Choice

While parents play a significant role in feeding children, children past a certain age also exert their own agency as they develop food preferences, make their own food choices, and influence the food choices of their family. While food preferences vary from child to child, recent studies from the United States and Canada have found that junk food holds a special place in the food life of children. For example, in focus groups, Canadian children consistently identified the same favorite foods – pizza, French fries, and junk food – specifically because they were considered unhealthy and were perceived as in opposition to adult foods (Elliott 2009). Furthermore, for children in the United States, Namie (2011) concluded that junk food carries multifaceted meaning and appeal for children in several ways. Purchasing junk food, such as candy, with their own limited money, makes these foods status objects for children and purchasing them, an expression of agency. Often ingested within view of peers, eating junk food not only represents a sort of conspicuous consumption, but also demonstrates belonging to a group. When given to a child, junk food also symbolizes and communicates caring.

Beyond the many meanings of junk food, a variety of factors influence children’s food choices. Children are often drawn to fun, an element of lesser importance to adolescents and adults. For example, in a US study focused on vegetable consumption, children were found to eat 50% more when the foods were fun in name, shape, or design (Wansink et al. 2011). Linked to a sense of fun, children are also uniquely influenced by the role of play in eating. Take for example the tactile play of eating a cookie or gelatin. The way foods look also influences a child’s food choice, whether attracted by cartoons, pretty designs, or images of food that look good to eat (Elliott 2009).

The school environment is one in which children may exercise more control over their own eating, as they make food choices without the supervision of parents or caregivers. When bringing a lunch from home, a child can choose whether or not to eat the provided foods or to “trade” them with a friend. If purchasing a lunch at school, children can exert negligible or considerable agency in selecting what foods to eat, depending upon the serving method. In their study of school food in London, Daniel and Gustafsson (2010) argue that adult attention and governmental policy alike have focused on the nutritional aspects of school food while ignoring elements that are likely of greater importance to children, such as social aspects. In their study of children’s food culture in a school lunchroom in the United States, Salazar et al. (2008) also concluded that there are distinct differences between how adults and children form food rules, norms, and values around eating. These authors studied the lunches that children created at a school salad bar, concluding that children enjoyed the freedom of choosing their own foods and arranging them in ways that they found appropriate, pleasing, and tasty.

Feeding Children: Case Studies

Food Marketing to Children

For child health advocates and parents alike, a serious ethical consideration in feeding children is the direct marketing of food products to children

as autonomous consumers. Children have increasingly become consumers unto themselves, influencing family purchases of many products, including food. Termed “pester power,” “the nag factor,” and “kid influence,” this influence describes the persistent nagging and whining that can accompany children’s requests for items that they desire. Advocates argue that marketers exploit children’s pester power in an effort to sell products that children want.

In the United States in the 1970s and 1980s, the Federal Trade Commission considered restrictions on the advertising of junk foods to children, but no rules were enacted. Those in public health, policy, and advocacy argue that regulatory efforts were thwarted by the food, toy, broadcasting, and advertising industries, which stand to make significant financial gains by advertising to children. These groups argue that they have the right to market to children under the First Amendment and proposed self-regulation as a solution. There has been a resurgence in efforts to police the food industry in this area, in part due to the 2005 Institute of Medicine of the National Academies review, which concluded that food marketing influences child food preferences, consumption, and health.

Much research has focused on food advertising during children’s television programming. In a 2005 study of Saturday morning children’s television programming on air in the United States, researchers found that approximately half of all advertisements were for food and nearly all (91%) were for foods or beverages high in fat, sodium, or added sugars or were low in nutrients (Batada et al. 2008). The advertisements were most commonly for ready-to-eat breakfast cereal and cereal bars, restaurants, and snack foods. Food advertisements also featured cartoon characters (74%) and toy or other giveaways (26%) (Batada et al. 2008).

While traditionally appearing in television advertisements and on product packages, food marketing now takes a variety of forms. In the United States, companies market to children in myriad ways: online; through social media; in games; with product placements in popular television programs, movies, and video games; and

even in their schools. The December 2012 Federal Trade Commission Report on food marketing to children and adolescents in the United States found that while the funds spent on television advertising decreased during the period 2006–2009, dollars spent in new media increased by 50% (Nestle 2012). Furthermore, Elliott (2012) argues that marketing unhealthy foods to children constitutes a “dual ethical transgression”. She argues that child-centric marketing manipulates a young target audience without the cognitive ability to understand the marketing techniques and in some cases lacks the ability to distinguish advertising from scheduled entertainment, such as television programming. Secondly, Elliott argues that because a significant portion of child-centric marketing encourages the consumption of unhealthy foods, this marketing contributes to the desire for and potential subsequent consumption of a diet that may have detrimental effects in the short and long term.

Children and Supermarket Shopping

The supermarket is an environment in which food marketing to children comes into play, as children assert their own agency to significantly influence and control their own and their family’s food selection. Parents have been shown to give in to child food purchase requests as much as 45–65% of the time (O’Dougherty et al. 2006). In this way, parents can be both a “strong” and a “weak” link in a child’s food chain at the supermarket in the promotion of a healthy diet (O’Dougherty et al. 2006). Illustrating this point, Berry and McMullen (2008) studied the visual landscape of the breakfast cereal aisle at a Toronto supermarket, seeking to understand how marketers engage children, who have been found to influence half of all breakfast cereal purchases. The authors concluded that the least healthy cereals – those containing more sugar, refined grains, and trans fats – were more likely to feature child-centric marketing, such as cartoon spokes-characters, themed cereal shapes and colors, and incentives on the cereal boxes.

Given that children do influence purchases, researchers find that parents typically involve children in food shopping in a variety of ways,

ranging from conflict-ridden negotiation to “co-shopping” in an effort to increase a child’s food knowledge and interest. Food shopping can also be a learning opportunity, engaging children in not only food knowledge, but also other educational acts, such as practicing counting and reading. In such a way, the supermarket provides a test environment in which the multiple ethical considerations of feeding children play out. Within this public microcosm, parents balance their own motivations when food shopping with the health, desires, and development of their children, as well as with the motives of the food industry.

Children’s Cuisine and Menus

In the countries addressed in this entry, children’s culture increasingly exists within popular culture, along with it a type of “kid-friendly” cuisine. Within families, children’s food is often differentiated from adult food, at times holding a lesser place. Children’s snack foods and treats in particular are “othered” compared to the “proper” foods that constitute family meals (Curtis et al. 2010). Within the consumer culture, a plethora of child-specific products are available, including food products designed for and marketed directly to children. For example, in the United States, the overtly and aptly named Kid Cuisine brand by ConAgra Foods strongly promotes fun. Packages feature bold colors and cartoon penguins. Meal options include “Mini Corn Dogs” and “Fun Shaped Chicken Breast Nuggets.” Lunchables, a Kraft Brand, also promotes fun, offering up finger foods that combine eating with play. Interestingly, both Kid Cuisine and Lunchables have modified their product offerings in recent years, adding options with at least one serving of fruits, vegetables, or whole grains.

Across the United States, special “kid-friendly” meals are made available at local, chain, and fast food restaurants. Meal options generally consist of foods such as chicken nuggets or fingers, hot dogs, grilled cheese sandwiches, macaroni and cheese, hamburgers, and French fries. Some chains offer a thematic children’s menu, such as the iconic McDonald’s Happy Meal. Such options demonstrate a cultural

interpretation of a child’s palate and gastronomic preferences. Furthermore, a 2008 study found that 99% of the children’s meals served at the top 50 largest chain restaurants in the United States were of poor nutritional quality (Batada et al. 2012).

The unhealthy nature of children’s menus is concerning to public health advocates as, like adults, children consume an increasing number of meals outside of the home. These meals tend to be less healthy and larger in portion size than meals eaten at home. Specific interventions have focused on improving the quality of children’s fast food meals, which are generally high calorie and low in nutrients. In 2010, Santa Clara County in California became the first US jurisdiction to implement an ordinance that allowed toys to accompany only meals that met minimal nutritional criteria for calories, fat, sugar, and sodium (Otten et al. 2012). Though this example has its limitations, such ordinances appear to positively influence the marketing of healthful menu items and are currently being enacted in other cities and states.

As childhood obesity and overall health remain a key concern, myriad strategies have been explored to shape and modify the feeding of children within families at home, as well as in schools and at restaurants. A variety of ethical questions also remain. Should soft drinks be sold in schools? Should extremely obese children be taken from their parents? Should restaurants be required to sell healthy meal options for children? Should cartoon characters be used to promote the sale of unhealthy foods? And should they be used to sell healthy foods? Each of these questions comes with its own ethical considerations, balancing the needs and desires of children with those of parents, governments, and societies as a whole.

Summary

As babies are born without the ability to feed themselves, parents are intimately involved in feeding children throughout their young lives. Parenting styles and the eating behaviors of

parents themselves greatly influence feeding practices, as do the needs and desires of children. Within the context of childhood obesity, feeding children becomes not only a social and familial process, but also a public health issue with myriad ethical implications, ranging from food marketing to children to the construct of children's culture and cuisine.

Bacterium/bacteria; Fermentation; Fermented foods; Ferments; Fungus/fungi; Microbes; Microbial ethics; Microbial foods; Microorganisms; Mold/molds; Yeast/yeasts

Introduction

Defined broadly, *fermentation* entails the chemical transformation of a foodstuff by microbes, whose metabolism alters the flavor, aroma, texture, or nutrient content of a given food (Steinkraus 2002; Katz 2012). In the context of food handling, fermentation is both a biochemical and semiotic transformation of a foodstuff. As a result of these chemical changes, fermentation can imbue new meanings into food that inform the values, traditions, and heritage of a community (Saber 2011). As an example, the fruit sugars in grape juice undergo a chemical transformation into alcohol and other by-products by the metabolism of yeast, and the resulting wine can serve as markers for hospitality or even take on religious symbolism in certain faiths. The ethics of fermentation address questions about knowledge and power in the interactions among humans, foods, and the microbes that transform both.

Backgrounder: Fermentation and Microbial Life

Microbes are generally classified into families of bacteria and fungi. Bacteria are single-celled organisms that reproduce asexually. Fungi are further classified into yeasts (unicellular) and molds (multicellular), which have more complex life cycles. Although microbes live on almost

every surface at all times, a single microbe cannot be seen without the aid of a microscope. Microbes can also be visible to the human eye when they reproduce in billions and form a *colony* or a mass of genetically identical microbial species. Sometimes multiple species form a mass together, thriving on each other's metabolic by-products. This is called a symbiotic culture (or colony) of bacteria and yeast, often shortened to the acronym SCOBY. Different microbes thrive in distinct environments, depending on factors like the ambient temperature, humidity, acidity, salinity, and availability of nutrients. Fluctuations in these parameters can enable or hinder certain microbial life from reproducing. In certain cases, the same microbe will act differently depending on different environmental conditions. For example, the common yeast strain *Saccharomyces cerevisiae* will convert sugars into alcohol when there is access to oxygen but will produce carbon dioxide when there is not. This is how beer and sparkling wine become carbonated when bottled. Regional differences can also affect microbial profiles. The bacterial strain *Lactobacillus sanfranciscensis*, which is unique to San Francisco, California, is said to impart the local sourdough bread with a particular tartness. The variety of microbial species and each of their unique habitats reflects the diversity of microbial life. This makes the range of fermentation possibilities equally diverse.

Ethical Questions Inherent to Fermentation

Some of the ethical considerations that inform the interactions with microbes through the practice of fermentation are related to human control, the regulation of microbial life, their utility to human life, and the epistemics of fermented foods. These considerations are interrelated and formulate the ethics of fermentation.

Historically, many societies have relied on fermented foods as a way to preserve nutrients in times of dearth. By intentionally fermenting abundant crops following a harvest season, the texture, taste, and nutrient content of a food are preserved, sometimes enhanced, for survival and pleasure.

Unlike cooking, fermentation can occur independent of human volition, which challenges some ideas about human control and power. But like cooking, there is an engagement with food materials in order to bring about food transformations that shape cultural rituals and culinary practices.

Across time and regions, fermented foods, as well as their concomitant microbial life, have informed human cultures. Yet, because they are microscopic and invisible to the human eye, they do not present as other living creatures do and connect to broader considerations about how to interact with that which we cannot see, sense, or otherwise understand. It may be difficult to imagine a set of ethics with microbes, yet their ubiquity poses some urgent and fundamentally ethical questions about agency, regulation, and life/death.

Microbial Regulation and Ethical Theory

Many philosophical problems that arise within fermented food ethics are based on power relations and control. Given that modern microbiology arose from the need to identify and remedy the causative agents for disease and decay, it is not surprising that the relationship between humans and microbes has been characterized by domination and eradication for the purposes of protecting human well-being. In nineteenth-century Europe, the parallel works of Louis Pasteur and Robert Koch isolated microbes as vectors for disease, setting the stage for what Bruno Latour calls “a theatre of proofs” to empirically justify microbial pathogenicity (1988, p. 88). Most notably, the legacy of Pasteur lives on as a modern sterilization process: *pasteurization* entails bringing a food substance (such as milk or fruit juice) to a high enough temperature or pressure to kill off all microbial life. A better understanding of how to control microbial life has led to advances in public health and food technologies, foregrounding infrastructures such as municipal wastewater treatments, food safety protocols like Hazard Analysis and Critical Control Points (HACCP) guidelines of high-risk foods, and policies that legislate raw milk sales. From a positivist perspective, these regulations reflect the practical

application of ethical theories in decisions that serve and preserve human interests. Ethical human conduct and moral reasoning are in the name of upholding the human species.

Other theorists have questioned this model of human understanding in the greater context of multispecies living and see ethical engagements with microbes as opportunities to challenge assumptions about human exceptionalism or human primacy. Evolutionary biologist Lynn Margulis argues that plants and animals are hybridized forms of microbial life; to forget these microbial origins and think in reductionist terms that bracket the human is “as dangerous as it is prevalent” (1998, p. 56). Some feminist theorists have extended Margulis’ counter-theory to question the ethical implications of how humans live with other species (Haraway 2003; Tsing 2015) and to propose an alternative micro-ontology of self from the perspective of microbial life (Hird 2009). Specific to food, Heather Paxson applies Foucauldian notions of microbiopolitics in her analysis of raw milk cheese production and regulation (Paxson 2008). Given Paxson’s argument, fermentation brings to the fore the applied ethics of what is considered appropriate behavior for engaging with microbes in instances of inoculation, infection, and digestion.

Utility and Health Concerns

Some ethical considerations pivot about the question of what is a microbe, which often straddles the ontological binary of *probiotic* and *pathogenic*. These categorizations are based on the uses and risks of microbes to human well-being. Their utility defines them as good or bad entities.

Fermented foods have long nourished humans. Fermenting and preserving cassava, for example, increases the protein content and flavor profile of an otherwise bland tuber. In other parts of the world, like East Asia, soy-based ferments such as *shōyu* (Japan), *jiang* (China), and *jang* (Korea) serve the dual purposes of making amino acids and minerals available year-round while adding umami flavors to the everyday meal. Many common foods undergo fermentation, including cacao

beans, cheeses, yogurts, breads, sausages, and alcohols. While it would seem that fermented foods permeate all food cultures, their uses are far from universal and depend on context.

In contrast, food poisoning occurs when specific microbial strains or their toxins are detected by the immune system of the human body; medical texts consider these instances as pathogenic and tend not to include these microbial strains under the umbrella term of fermented foods. For instance, the bacterial strain *E.coli* O157:H7 is a notable agent in recent cases of foodborne illness; other examples include the bacterial species *Vibrio cholerae* responsible for cholera and the endotoxin produced by *Clostridium botulinum* that is responsible for botulism. Encountering these microbes can be fatal and have debilitating consequences in our food system and agricultural production.

Partly because of the historical emphasis on isolating pathogens, microbial pathogenicity is quite clear even when the research on how microbes can help us remains murky. Current research on the *microbiome* – or the unique microbial profile of an individual – is trying to explore the connections between microbial species, the gut, and wellness. Foods rich in probiotic bacteria, for example, carry with them the starting materials for neurotransmitters and anti-inflammatory agents that can aid our physical and mental health. Sometimes, a fermented food is naturally probiotic due to the presence of certain bacterial species; other times, these species are isolated as dietary supplements or added to commercial products.

However, this dualism of probiotic and pathogenic does not capture the complexity of microbial life as microbes are not just one entity. For instance, the bacterial species *Lactobacillus delbrueckii* is one of the bacterial strains considered to be probiotic that is commonly in yogurt; but it is also one of the causative agents of urinary tract infections (UTIs). The bacterium neither definitively nor ontologically fits into one category or the other, but its utility depends on context. Microbes do not necessarily have a fixed identity or role. Rather, how microbes interconnect with human lives can be complex.

Fermented Foods, Epistemics, and Practical Ethics

Fermented foods raise ontological questions about what constitutes edibility as well as epistemological considerations about how one comes to know its fermented state. Fermented foods are at once alive and decaying. They are alive in that they can transform independent of human intentions, but they are not alive in the sense of sentience. They are decaying in the sense of biochemical breakdown, but they are not decaying as in moving toward inactivity. This complicates how to know fermented foods as an object, because they are constantly in a state of becoming and transformation.

Working with lively materials and multiple species raises the ethical question of which epistemological framework can account for understanding the dynamic and the unpredictable. Fermentation techniques work indirectly with microbes: one does not manipulate bacteria and yeasts as ingredients but can only set up favorable/hostile environments for microbes to thrive/suffer. This involves making adjustments to temperature, salinity, acidity, and humidity to create favorable conditions for certain microbes over others. Fermentation teaches practitioners how to work *with*, instead of working *on*, living substrates because these practitioners must continually improvise and adjust. A rationalists approach would rely on quantitative parameters (e.g., pH meters, thermometers) to measure and compare data against similar data. In contrast, an empirical approach would rely on the corporeal senses to feel, taste, and sense their way through transformation. How these practitioners come to know the ideal conditions for certain kinds of microbial life means perpetually “tuning the senses” (Salter 2014, p. 84). In the broader context of food preparation, practitioners who rely on embodied knowledge “*know* things literally with [the] body” instead of that knowledge being contained in their heads (Heldke 1992, p. 218 original emphasis). They rely on troubleshooting, remediation, and their corporeal senses to work through the dynamic nature of ferments. There are no stable norms; instead, fermentation addresses different types of

epistemologies to know how to work with microbes and when a fermented food is ready to consume.

Many food scholars have commented on how this epistemological knowledge gets applied to the social construction of personal and collective identity. On an individual level, fermented foods can bolster one’s identity as a certain type of eater. However, while fermented foods span a variety of food ideologies, they do not make up one definitive set of practices in any of those foodways.

On a larger scale, fermentation has historically shaped cultural rituals and culinary delicacies across food cultures, animating discourses on what should or should not be eaten. Fermentation is often a communal, social practice whose practices, know-how, and taste preferences circulate within communities to reify social ties. The foods themselves can also be used as leverage to reinforce social identity. Fermented foods such as Japanese natto and Swedish surströmming are known for their strong odors of ammonia and rotten eggs, respectively. Yet, the acquired taste for or against these foods serves as markers of in-group and outside-group identity, allowing sentiments like “we are the people who eat these delicious foods” and “you are those people who eat those disgusting foods” to circulate. As learned tastes, fermented foods regulate society in the form of practical ethics.

Conclusion

The ethical issues related to fermentation include questions around human control, how microbial life is regulated, the utility of microbes to human life, and the epistemic considerations of fermented foods within an individual and in society at large. Some of the ways that these issues are addressed can be seen in the recapitulation of human control, whereas other points of view acknowledge that life with microbes is inextricably linked and works to acknowledge life *with* other species. These ethical issues arise from the fact that microbes

cannot be seen or otherwise sensed by the human eye, which point to larger questions about how we tend to fear what we cannot understand or communicate with. Given the ubiquity of ambient microbes, these questions present ethical concerns and traverse geographic regions, timescales, and food cultures.

Food "Porn" in Media

Signe Rousseau
School of Management Studies, University of
Cape Town, Tamboerskloof, Cape Town,
South Africa

Synonyms

[Gastro porn](#)

Introduction

The term food "porn" can refer to still or moving images of food and/or eating across various media, including cookbooks, magazines, television, blogs, websites, and social media platforms like Twitter, Facebook, Instagram, and Pinterest. Evocative descriptions of food and eating in literature can also be described as food porn. The term is often used positively, to suggest that the food

depicted is desirable or is depicted in a way that makes it desirable – the latter of which could depend on the aesthetics of composition (including lighting, extreme close-ups, color saturation) or on the person or people preparing or eating the food. While the connotation is often of "guilty pleasure," or allowable "indulgence," the term can also (sometimes simultaneously) negatively connote food which is regarded as "bad" and which should be avoided.

Not unlike the now-famous definition of pornography – "I know it when I see it" (uttered by Supreme Court Justice Potter Stewart in the 1964 "Jacobellis v. Ohio" case regarding whether or not the French film *Les Amants* should be considered pornographic) – the term's application is therefore very broad, ranging from playful referrals to food that looks particularly appetizing to what are intended as more serious warnings about the possible implications of eating particular foods. Its widespread presence in popular media suggests that there is less stigma attached to consuming food porn than there continues to be attached to consuming non-food or "traditional" pornography (debates around which include the question of whether pornography represents and encourages violence against women or whether it functions as a "sex-positive" means of feminist expression). Rather, its vicarious, or unreal, component arguably fuels a perception that consuming food porn is safer than consuming real food. The extreme of this is borne out by sufferers of eating disorders who rely on images of food as a substitute (within limits) for eating. But food porn is not without its own stigma, and ethical considerations related to its production and consumption include examining its role in a culture which accommodates and produces "foodies" and at the same time various crises of overeating and undereating. Some critics suggest that each of these patterns of consumption represent various degrees of disordered eating. From this perspective, and echoing the argument that pornography contributes to a distorted and unrealistic view of sexuality and sexual behaviors, the market for and widespread "use" of food porn potentially fuels an obsessive and, in some cases, "unhealthy" relationship to food.

This entry begins with the background of the use of food porn, including some technical shortcomings of the analogy between food porn and non-food pornography. It then offers a number of examples of its widespread use to indicate the "normality" of the concept in contemporary popular and food media cultures. It then reviews satirical and critical responses to the concept before concluding with a summary of the key ethical considerations related to the production and consumption of food porn.

Background

"Gastro porn," a variant of food porn, was first used in print in the *New York Review of Books* in 1977, when a cookbook review reflected that "True gastro-porn heightens the excitement and also the sense of the unattainable by proffering colored photographs of various completed recipes" (Cockburn 1977). Here both the "excitement" and the "unattainable" allude to the element of fantasy which is a key commodity in non-food pornography. Food-related fantasies were not confined to cookbooks: after decades of enjoying a postwar "luxury diet" (Belasco 2006), many Americans turned their attention in the 1980s to diet, fitness, and which foods to avoid to maintain a lean and fit body. This period also saw a sharp simultaneous rise in obesity rates, in the incidence of eating disorders, and in food-related media (e.g., magazine articles and cooking shows on television) which provided voyeuristic escapes into worlds of food and eating where money and calories were of no consequence (O'Neill 2003). From its first manifestations, what is now referred to as food porn thereby occupies a contested space between cultural constructions of "legitimate" and "illegitimate" desires when it comes to eating. By providing various forms of food fantasies, it also reflects a growing appetite for the vicarious and "guilt-free" consumption of food.

As a reflection of the increasing guilt associated with consuming certain foods, the Center for Science in the Public Interest (CSPI) launched its monthly "Nutrition Action Health Letter" in the

1990s, a key feature of which was, and continues to be, exposing food identified as the "Right Stuff" vs. "Food Porn." Their November 2012 newsletter, for instance, offers Cascadian Farm Organic Harvest Berries as the Right Stuff, while Quiznos Chicken Carbonara Sub is dubbed porn for offering (among other "bad" qualities) "close to a day's saturated fat (17 g), and nearly 2 days worth of sodium (2,610 mg)."

Far more prevalent than the CSPI's unambiguous use of the term "food porn" as something to be avoided, however, is its ubiquity in popular food-related media channels. This includes using the pornography analogy to explain the recent explosion in food-related media and, particularly, food television as a substitute for cooking. According to celebrity chef Anthony Bourdain at a 2009 "Food for Thought" panel held in Connecticut (featuring several food media personalities conversing on stage about the exponential rise in food media), "It's the new pornography. It's people seeing things on TV, watching people make things on TV, that they're not going to be doing themselves any time soon." From this view, food porn exists less as a manifestation of the vicarious consumption of "guilty" pleasures than as a comment on the general public's apparent lack of competence in the kitchen. Yet the limitations of the food porn-as-substitution analogy are summarized by a former pornography production assistant who points out that "Porn incites to action and is worthless if it does not" (McBride 2010) and by a reminder that even in gastronomy, "vicarious enjoyment is more definitely intended to be a prelude to, not a substitute for, direct and actual enjoyment" (Mennell 1985).

Beyond the historical and philosophical relationship between food and sex (both are driven by appetites which can be "overindulged or denied," and both can be represented either as "playful and witty and teasing" or "somewhat menacing," Korsmeyer 1999), the analogy between food media and pornography also includes technological similarities between the two industries. One such similarity is the use of extreme close-ups and, in food television, manipulating and extending the "climactic" moment of a cooking segment (Kaufman 2005).

Embracing the Trend

Despite the limitations and possible negative connotations of the analogy, popular and professional acceptance of the term is reflected in its widespread use. British chef Nigel Slater has what one writer calls a "virtually pornographic recipe for Purple Figs with Warm Honey" (Humble 2005) – though here the association between food and sex is made plainer than most, with the opening lines of the recipe advising that the dish is "A snack to share with someone special, in bed, on a cold winter's night." A review of *Tortilla Soup* describes the "comestible-filled" film as "almost foodie-porn. The camera lingers over such dishes as tangerine glazed lamb ... like a lecher over a glistening naked body" (O'Sullivan 2001).

Websites include personal food blogs like Foodporn.com (with sections labelled "barley legal," "hardcore," "lebanese," and a subtitle claiming to have been "Redirecting Perverts to the Refrigerator Since 1999"), FoodPornDaily.com (subtitled "click, drool, repeat"), and FoodPorn.net (simply billed as "food photography," but with the promise that "If we don't make you hungry, no one will"). Professional productions include those like the "Food Porn"-themed episode in Season 6 of celebrity chef Anthony Bourdain's *No Reservations* show, hosted by veteran pornography actor Ron Jeremy and sold as "a XXX selection of all that's lip-smacking and luscious in the world of food. For hardcore viewers only." When Bourdain cuts into a piece of beef he describes as "twenty-four frikkin pounds of slow roasted, melt-in-your mouth, slightly bleeding love," the event is billed as "totally the money shot." These references not only confirm food porn as an accepted genre, but also rely on at least some consumer knowledge of the actual pornography industry for their understanding.

More representative of its general use, the term is widely employed to describe any food that looks good to eat, even if it is only an illusion. The popular competition show *Top Chef* features a named food porn dish on each show and has a dedicated "Food Porn room" equipped with

various tools to make the food look picture-perfect, such as Windex (used to clear fingerprints off the plate) and beet juice, used to restore a "touch up meat that has lost its rosy glow" (Keller 2012). These modifications – some of which likely contribute to rendering the food inedible while making it look better – reinforce the priority of fantasy, or unreality, rather than any perceived eroticism or explicit sexuality of food porn. According to one early commenter on the rise of food television, "It's not erotic. . . that's not why it's called food porn. It's just unreal. You will never meet a Playmate of the Month; you will never eat the red, juicy tomato that you see on 'Barefoot Contessa'" (Buford 2006).

It is true that the precise tomato seen on television will always, and necessarily, be unattainable. Yet it remains arguable that a close enough proxy can be attained, as the growth in food media has seen a simultaneous growth in the availability of "gourmet" and "foodie" ingredients – often through non-corporate retail spaces such as farmers' markets – indicating at least some degree of overlap between on- and off-screen culinary activity (which also counts as evidence against the food porn-as-substitution argument). At their most extreme, these overlaps are often described as the "effect" of (typically) a particular celebrity chef whose televised demonstrations have resulted in direct and measurable sales spikes in specific ingredients. (The term "Delia effect" was included in the *Collins English Dictionary* in 2001 following a 200 % rise in the sale of cranberries in the UK thanks to a recipe from celebrity chef Delia Smith. Similar effects have been noted following the publication and/or broadcasting of recipes by celebrity chef Jamie Oliver, while the hit baking-competition television show *The Great British Bake-Off* is correlated with a marked increase in the sales of baking equipment in that country.) And given that many, if not most, of the pictures posted as food porn on blogs and websites are generated by non-professionals, there is ample evidence that plenty of cooking activity is taking place. But it is impossible that all food porn incites to action because there is simply too much of it available for us to "click, drool, repeat."

Pinterest is notable as one of the fastest growing Web-based sharing sites, with food-related content the most popular among consumers. Other popular sites and tools for viewing and sharing food porn include Instagram, food pictures shared through which are collected on a dedicated "foodies" site, Instagram Foodies, and Tastespotting, notable for being subject to editorial vetting to ensure that "what finally gets served up on the site is a beautifully refined set of the community's contributions." As an index of the importance attached not only to sharing food photographs – because social media tools allow anyone to self-publish – but of the community recognition that comes from being published on other sites is Tastestopping, subtitled "Feasting on Seconds," which "offers a second home for food photography that has been rejected by other sites" (such as Tastespotting). While sites like Instagram Foodies and Tastespotting do not bill themselves explicitly as food porn, they exist thanks to and as part of the same market that equates appealing pictures of food with food porn. When a New York restaurant created an "Instagram menu" using photographs of their food taken by customers and uploaded to Twitter using a certain hashtag, the decision was reported under the headline "Restaurants Use Instagram To Tap Into Food Porn Obsession." Media texts in this way contribute to consolidating the notion of any image of food as "porn" and of the trend as "obsessive." The term also exists as a widely used hashtag on Twitter (#foodporn) and tag for blogposts and YouTube videos to provide more searchable content. (It should be noted that blind searches for anything which includes the word "porn" is likely to yield at least some non-food-related pornographic content.)

A final popular manifestation of the food porn trope is in the representation of food media personalities in sexually suggestive poses. This includes single features, for example, the spread in *FHM* in 2003 featuring US celebrity chef and talk-show host Rachael Ray wearing very little in a series of kitchen scenarios (holding a pie, taking a turkey out the oven, licking a wooden spoon). British celebrity chef Nigella Lawson, who is routinely referred to as the "queen of food porn"

(Rousseau 2012), appeared in December 2007 on the front cover of *Stylist* magazine with caramel dripping down her face and hands (the story was a feature on Lawson's "love affair with salted caramel"). The trend is not confined to women. Anthony Bourdain posed naked holding only a large bone for *My Last Supper*, a book on chefs and their ideal final meals by Melanie Dunea. (Despite his early moniker of "The Naked Chef," Jamie Oliver has not posed or appeared naked in public.)

Satire and Criticism

Despite the lack of a single definition of food porn, and some debatable arguments about its function, its existence as a cultural phenomenon is incontrovertible. This is indicated both by its widespread positive use, and also by satirical and critical responses to the trend.

In 2006, British journalist and broadcaster Charlie Brooker presented a segment on his *Screenwipe* television show in which he sits in front of the television and questions whether it is true that "food is the new porn" (Season 2, Episode 3). Interspersed with Brooker's dialogue are sights and sounds from a television advert for a "gourmet salad with caramelized pears and creamy Stilton," which includes said ingredients falling into a bowl. "Oh, you dirty piece of cheese," offers Brooker, before the advert introduces "pork pie in rich crust paste" and "extra sweet handpicked fresh cherries." As voice-over concludes that "this is not just food," Brooker responds by standing up abruptly, unfastening his belt and saying "You're damn right it's not, it's food that about to be f**ked silly." While consistent with Brooker's provocative style, by intentionally misinterpreting the trend as encouraging actual sexual activity with food, the segment challenges what food porn actually means and what an appropriate response to it is, or should be.

Other examples of criticism include implications that food porn exists as an index of inappropriate and uncritical adulation of food and cooks. Commenting on the language used in one

restaurant review, UK restaurant critic AA Gill concluded that "That's not a review of Chef's Table at Brooklyn Fare – it's a handjob" (Gill 2012), while the food critic for *The New York Times* has indicated that seeing words like "sinful" to describe food makes his "skin crawl" and that "The Times would probably frown on orgasmic, with good reason" (Wells 2012). Regarding this "sexualisation of food in our culture," one argument holds that rather than representing the "pornification of everything," food porn represents the "foodification of everything" (Poole 2011). This notion of over-attention to food is satirized in a song titled "Eat It Don't Tweet It," also billed as the "Instagram Food Porn Anthem," and on the website Pictures of Hipsters Taking Pictures of Food (www.pohtpof.tumblr.com).

Academic criticism includes the view that because "representations of sex combined with food are not per se transgressive," food porn is "boring" (Probyn 2000), and the argument that the term's critical usefulness lies in recognizing the potentially problematic relationships with food concealed beneath the "playful banner" of food porn (Rousseau 2012).

Artistic responses have included series of photographs like those by artist Laura Letinsky which, contra the prevailing style of "flawless" food, depict scenes of half-eaten food and stained tablecloths designed to explore the "problem of the illusion of perfection," while Stephanie Gonot's "Fad Diets" comprises representations of popular dieting trends, for example, a dirty ashtray and a Diet Coke can or lemons, maple syrup, and cayenne (ingredients of the "Master Cleanse" diet).

Food Porn, Disordered Eating, and Ethical Considerations

A more serious form of criticism of the food porn trend are numerous suggestions that its ubiquity reflect and contribute to a widespread disordered relationship to food. In some cases this extends to what are recognized as bona fide eating disorders like anorexia, bulimia, binge-eating disorder, and

EDNOS (Eating Disorder Not Otherwise Specified), used to describe individuals who do not meet the diagnostic criteria of eating disorders listed in the current DSM (Diagnostic and Statistical Manual of Mental Disorders).

A YouTube video posted in April 2012 features Kati Morton, an "Eating Disorder Specialist," on the topic of food porn. She introduces the topic as one which may "sound a little weird, maybe even creepy or dirty" and then qualifies that she is "calling it food porn, but you could also call it eating disorder porn in general: things that we do to feed our eating disorder." She further distinguishes between behavioral activity such as bingeing, restricting, or purging and the activity of seeking out "external stimuli" or "any kind of media" to fuel an eating disorder. Cooking shows are noted as a prime example, followed by recipe websites, filled with recipes of things "we will probably make but maybe never eat." It is the facility of media to induce the activity of "just fantasizing about food" that qualifies it as "porn" (in Morton's definition, eating disorder porn is not limited to food media, but also includes, e.g., fashion magazines featuring underweight models). In this context, food porn is registered as potentially harmful to the eating disorder sufferer because it really is intended as a substitute for eating. Morton's advice to viewers is not to stop the activity of consuming food porn "cold turkey," but rather to register the behavior as an unhealthy activity.

More directly critical of the industry that produces food media is surgeon, author, and television personality "Dr. Oz," who in a 2012 episode of his talk show invited food media personalities to debate the "dangers of food porn," which in his view include that it can "make you fat." To this end, he introduced someone he described as a "victim of food porn," who had allegedly gained 20 lbs as a result of her "addiction" to food television. The opening voice-over explained the "science" behind the argument, namely, that it "turns out, simply looking at tantalizing foods lights up the same pleasure centers in your brain as sex, making you yearn for the pleasure of those high calorie, indulgent dishes you see. And just seeing images of luscious, delicious food releases

the hunger hormone ghrelin, which drives you to devour those same foods." Dr. Oz further claimed that popular competition shows like *Top Chef* and *Masterchef* leads viewers to falsely believe that they can recreate a "food porn fantasy," just as consumers of pornography could be led to think that they can recreate unrealistic sexual scenes (this is the argument that pornography normalizes a distorted view of sexuality). But whereas pornography is "self-limiting" – because sexual climax is typically an end point – what he sees as the "danger" with food porn is that people can return countless times to food to reenact that "orgasmic response" and, in so doing, eat to excess.

Restaurateur Joe Bastianich, one of Dr. Oz's invited guests, raised the definitional problem of whether any "beautiful picture of food" is "necessarily food pornography" and, touching on some of the ethical debates also surrounding the consumption of non-food pornography, whether food porn has a "necessarily negative connotation" (there exists a noteworthy schism between feminist philosophers who are "anti-porn," viewing the industry as negative and damaging, and those who are "sex positive," or "pro-sex," who see both consuming and taking part in pornography as a means of self-assertion). Arguing that it is ultimately up to the consumer to choose what and how to consume, Bastianich pointed out that First Amendment protects both the right to engage in S&M and to enjoy "double cheeseburgers with bacon." But he added that if what is celebrated as American food culture is a culture of excess – competitive eating, 8,000 cal dishes, and the like – then "we do ourselves and our country, where childhood obesity is an epidemic, a great disservice."

These examples and debates suggest that ethical issues related to the production and consumption of food porn share some of the considerations related to non-food pornography. This broadly relates to function: does either serve a purpose? If so, is it a "good," "useful," or "bad" function? (Conversely, is it acceptable to be interested in something with no discernible purpose?) Further interrogating function includes questions about health and well-being: critics of pornography are concerned with whether its consumption

contributes to sustaining an unhealthy relationship to sex. Similarly, does enjoyment of images of food in any way contribute to disabling rather than enabling a particular person? Also pertinent are questions of control and responsibility: some argue that pornography incites to violent and destructive behaviors. When it comes to food porn, if images and descriptions of food tempt someone to eat, can they control their urges? Should they need to? Whether yes or no, can they take responsibility for their actions? If they cannot, who should? Finally relevant is the value attached to freedom of speech and choice: does anyone have the right to interfere with a person's decision to consume whatever he or she wants, whether on a screen or on a plate?

It should finally be noted that various categories of pornography involving food do exist, which should not be confused with food porn as discussed in this entry: feeding porn comprises pictures and videos of overweight and obese women (men rarely feature) in provocative poses. Feeding porn is a subgenre of "fat fetishism" and is distinct from the phenomenon of "belly stuffing," featuring thin women eating until their bellies are distended.

Summary

A 2012 advertisement for Sugar In The Raw (a brand which includes an "all-natural" sugar and non-nutritional sweetener) features a picture of two cupcakes on a plate with the cherries on top censored as if they were nipples on a pair of breasts. The image – one in a series of similar photographs – does well to summarize the key features of food "porn" in media. Firstly, it is ubiquitous, meaning it has strong enough cultural currency to be exploited in advertising. Secondly, like pornography, it operates largely on the provision of illusion and on the generation of fantasy. Whether intended as prelude to, or substitute for, actual enjoyment of food remains debatable. Thirdly, while playing on the association between the shared pleasures of food and sex, it simultaneously reinforces various stigmas attached to both.

Abuse; Addiction; Alcohol; Dependency; Food

Introduction

This entry examines the question whether foods can be substances to which people become addicted. Is “food addiction” a defensible and plausible concept? Immediately several important questions and concerns arise. The first is the more general question: “What is addiction?” The second is whether certain foods or their “use” fall within accepted models of addiction. Can foods be “used” and have similar deleterious effects as the more paradigmatic drugs of alcohol, cocaine, and nicotine? The third concern involves the sorts of food that can be addictive. Fourth and fifth are the health implications for individuals and the public health implications that food addiction is causing an obesity epidemic. The sixth concern involves individual, social, and corporate responsibility for the causes and consequences of food addiction. The entry ends with a discussion of what food advocates and the food industry might learn from the Tobacco Master Settlement Agreement in 1998 that effected a significant cultural shift about smoking.

What Is Addiction?

This is the perennial question that has most often been framed in terms of alcohol use and then extended to other drugs such as cocaine, heroin, nicotine, or methamphetamine. For this discussion, the focus is solely on particular substances as addictive, thus sidestepping the question whether behaviors or processes such as shopping, having sex, or gambling can be addictive.

“Addiction” is a remarkably connoted concept that is used with a fair amount of elasticity by neuroscientists, medical doctors, psychology, addiction counselors, and lay people who identify as addicted. Psychologists and psychiatrists tend to rely on the Diagnostic and Statistical Manual of Mental Disorders-IV where the terms “substance abuse” and “substance dependency” are used (American Psychiatric Association 2000). In terms of diagnosing substance abuse or dependency, the focus is primarily on the worsening effects the drug use has over time. With substance abuse a person may over the course of a year fail to meet important social or professional obligations, find herself in more physically hazardous conditions, face legal problems from her use, or experience social and interpersonal troubles. A person who becomes dependent has problems that exceed these and experiences at least three of the following in the course of a year: a higher tolerance, which in turn requires greater amounts of the drug to achieve the desired high, withdrawal in the absence of the drug, an inability to control consumption, attempts to control or cut down, more time spent managing drug use, and continued use despite increasing physical and psychological costs. If individuals’ consumption of food begins to follow similar patterns, this is evidence for the claim that food is a substance that people can consume abusively and dependently.

Neuroscientists are more inclined to use the term “addiction,” tying the term to responses in the brain. Neuroscientific studies on addiction generally characterize addiction as involving two distinct behavioral traits: compulsion to use and impulsivity. Compulsion is often taken as cravings (in the case of humans) and

drug-seeking behavior (in mice). These are regarded as quantifiable in both animals and humans.

Scientists draw a distinction between cognitive impulsivity (delayed gratification) and behavioral impulsivity (inability to withhold a response). Cognitive impulsivity is measured as the increased choice of small immediate over large delayed rewards (Olmstead 2006). The working hypothesis now is that impulsivity is largely governed by both serotonin and the prefrontal cortex systems. When the serotonin level is too low, chances are greater that there will be less impulse control, and thus a higher chance of addiction. If the serotonin levels can be manipulated in the brain, there is a greater chance of heading off addiction. While these studies are in their infancy, this emerging explanation for why some people become addicts hypothesizes that the brain’s pleasure circuitry is malfunctioning. This circuitry is largely a matter of dopamine; those who have addictions seem to have a suppressed dopamine signaling ability. This means that it takes much higher levels of stimulation to reach the level of satisfaction that others reach with moderate indulgence. Many substances and circumstances can bring about pleasurable responses, but alcohol, cocaine, and nicotine seem especially to light up the pleasure circuitry, hence their addictive allure for some. This allure prompts many researchers to describe the brain as being “hijacked” by these drugs. Can certain foods cause the same responses? If so, then this is an argument for the concept of “food addiction.”

For the purposes of this entry, “dependency” as described in the DSM-IV and “addiction” understood in terms of impulsivity and craving are complementary if not identical. The terms pick out the same phenomena but perhaps highlight different features. Tolerance, for example, is a physiological response. Attempts to curtail drug use and fail may well be a consequence compulsion and a lack of impulse control. Thus, for the remainder of this entry, the term “addiction” shall be used since that is the term that has been attached to “food.”

Food as Addictive

Does the consumption or use of food produce corresponding behavior for a diagnosis for dependence and/or biochemical reactions in the brain? If the consumption of food fits within both the DSM-IV model and the one emerging in brain science, this is a compelling case for food addiction. Should the consumption of certain foods fit these two models, it is appropriate to shift language from “consumption” to “use.” Beginning with the DSM-IV criterion concerning tolerance, studies show that individuals come to require greater amounts of food to reach a point of satiation. There are also reports of dysphoria and anhedonism that follow from stopping or curtailing food consumption. One recent study showed that lab rats addicted to sugar water showed significant withdrawal symptoms including shakes and tremors and anxiety when researchers were able to block the sugar high via a drug (Avena et al. 2008). Additionally, the attempts to curtail or cease the consumption of certain foods become more frequent even as a person becomes more aware of the risks and hazards that follow from the overconsumption of certain foods (Gearhardt et al. 2009). Thus, there is a *prima facie* case for food consumption becoming addictive.

With respect to neuroscientific approaches to addiction that center on brain function and particular regions of the brain, food consumption produces similar responses in the pleasure circuitry. Laboratory animals preferred intense sweetness over cocaine (Lenoir et al. 2007). Additionally, experiments with laboratory animals demonstrate strong physical cravings (Cheren et al. 2009). And more recently, brain imaging has shown that the pleasure circuitry in the brain can be affected by certain foods in the same way as alcohol and other drugs (Cheren et al. 2009). The brain may become desensitized as a consequence of reduced activity in the region of the brain that registers reward. Impulse control is hampered and the ability to inhibit behavior is diminished. In people who identify as having troubles with food, photographs of the foods on which they binge may act as a trigger (Wang et al. 2011). Additionally, the

physical symptoms of withdrawal mentioned above provide evidence for the claim that the consumption of certain foods produce biochemical responses in the brain that are analogous to the responses produced by drugs such as alcohol and cocaine.

Are All Foods Addictive?

Do all foods have the same potential to be consumed in deleterious ways in ways noted in the DSM-IV and adversely affect the brain’s pleasure systems? Not all foods are created equal in this regard, with emphasis on “created.” Some foods are what researchers have called “hyperpalatable” (Gearhardt et al. 2011). Foods in this category are highly processed foods with significantly elevated amounts of salt, fat, sugar, or other sweeteners and with many added ingredients for preservation and appearance. An apple, for example, is one thing/has one ingredient which is “apple.” A medium apple has 19 g of naturally occurring sugar, 0 g of fat, and 2 mg of sodium. Eating an apple will produce some pleasure. A medium chocolate ice cream cone from Dairy Queen has 22 ingredients and has 34 g of sugar, 10 g of fat, and 160 mg of sodium, making it a hyperpalatable food for many persons. In these people, consumption of that ice cream cone will produce a far more pleasurable response than eating an apple. Humans produce opioids, the active ingredient in cocaine, for example, when digesting excess amounts of sugar and fat (Cheren et al. 2009). Many people eat not just for sustenance but for pleasure, and opioids provide pleasure. On either addiction model, the tolerance of people who are progressing toward addiction will increase, beginning the cycle of needing to eat greater quantities of certain foods or find new and different foods with greater amounts of sugar, fat, and salt in order to reach satiation and their pleasure threshold.

It is important to note that there are arguments against food addiction. The scientific study of addiction in general and food in particular is still in their infancy. Given that neuroscience has only recently entered the scene and has not yet offered a definitive explanation of the effects of drugs

such as alcohol or cocaine, one ought to be very cautious in extending the concept of addiction to food. Someone might also object to the extension of addiction to food on the basis of the DSM-IV criteria. One might ask if people truly experience an “increased tolerance” that is truly measurable. One might also ask if there is a viable comparison between the suffering of the heroin addict in withdrawal and withdrawing from hyperpalatable foods. These two criticisms are important and ought to have a proper airing. They do rest, however, on the assumption that there are “real” or “true” addictions that serve as the model for other substances. The most radical challenge to food addiction would take the form of denying the reality of any addictions.

Implications for Individuals

Discussions of addiction are almost always accompanied by questions about choice and responsibility. While “addiction” is a relatively new term, “drunkenness” and “inebriety” are not. Typically drunkenness was regarded as a character flaw in a person who suffered from weakness of will. While psychiatry, psychology, self-help groups, and most recently neuroscience have effected a shift away from this view, there are still strong vestiges of it. Alcoholics and drug addicts, especially in contexts framed by the 12-step approach of Alcoholics Anonymous, recommend total abstinence in order to recover or have sobriety. This raises the question of what is the equivalent of sobriety for food addiction. It is possible to live without alcohol or nicotine but not so with food; total abstinence is not an option. This is where a model of harm reduction might be helpful. Harm reduction focuses on lessening the harm or injury caused by alcohol or drugs through moderation. Moderation may lead to abstinence, though it may not be necessary for all. With respect to food addiction, a harm reduction program may prompt one to eliminate certain categories of food while allowing others in moderation.

Food addiction may also lead to major health concerns including diabetes, hypertension, and short life expectancies. When considered from

not just the perspective of individuals but from the perspective of the population as a whole, there are potentially significant public health concerns.

Public Health Policy Implications of Food Addiction

Some argue that “the obesity epidemic” is a consequence of food addiction (Cocores and Gold 2009; Gold et al. 2009). The assumption is that an individual becomes obese because he eats compulsively and is unable to refrain from doing so even or especially when he has a desire to do so. He may be motivated by significant physical cravings. A recent study show that overconsumption of fat may further stimulate the intake of fat (Cheren et al. 2009).

While individuals are obese, the “obesity epidemic” is understood as a condition or disease of a culture or society. The “epidemic” is considered as real/has the same ontological standing as individuals who have the illness. Calling something an epidemic carries with it the assumption that a culture or society is at great risk from that illness. Arguing for or against the obesity epidemic is beyond the scope of this entry. Regardless of the reality of the “epidemic,” these costs – economic, social, political, and ethical – raise important questions about responsibility.

Responsibility for the Consumption and Production of Hyperpalatable Foods

If certain highly processed foods have the potential to be as addictive as cocaine and heroin, then how should the production, distribution, and consumption of these foods be conceived? Where does responsibility for food addiction rest? The question about responsibility with respect to other addictions has always been a contentious one. For quite some time, addiction was thought to be a matter of choice and that people choose whether and how to consume a particular substance. If a person develops into an addict, the typical thinking that he has been making choices along the way and responsibility rests firmly with him.

Responses to food addiction and public health concerns about obesity have largely been directed to individuals and their choices and actions. The argument goes: Were individuals to eat less and exercise more and enjoy food in moderation, then there would not be the same overconsumption that causes people to become obese. The source of the problem is identified as overconsumption and other lifestyle choices that individuals make. On this view, weight gain, loss, and maintenance is a consequence of calories used and calories burned. The food industry argues that a calorie is a calorie, regardless of the package in which it comes. While it is possible for some to strike the right balance between calorie consumption and expenditure by making all the necessary lifestyle changes, it may be so labor and time intensive that most people are unable or unwilling to do so. This focus on individuals changing their lifestyles and their behaviors and attitudes about food might mirror the experiences of alcoholics in recovery. If food addiction is as real as alcohol addiction, then the means and methods for recovery or sobriety might be similar. Overeaters Anonymous, for example, formulates its 12 steps on the basis of Alcoholics Anonymous. A harm reduction approach, as discussed above, recommends moderation.

The issue of choice, however, has come under greater scrutiny against the backdrop of addiction as a matter of biochemical responses in the brain. If some people are born with or come to have lower levels of serotonin or dopamine, their chances of developing an addiction are greater. If these levels are not within an individual's control, then in some sense she is not responsible for developing an addiction. The chemistry deck was stacked against her, perhaps even before she took her first drink or puff of a cigarette. On the pains of inconsistency, one would need to hold that the same holds true for food addiction.

There has always been a strong link between choice and responsibility. A traditional approach is that people are responsible to the degree to which they can make choices when they are reasonably fully informed and acting in the absence of coercion. Where information is lacking or there is some element of coercion, responsibility is

mitigated. Instead of conceiving of responsibility as it relates to addiction as being a toggle switch having only two positions (on = total responsibility and off = no responsibility), responsibility for addiction rests in many places to varying degrees. Yes, individuals do make many choices along the way about what they eat, for example. People choose to eat foods they know are high in fat or calories. They choose to eat these foods often and to excess. But individual actions do not exhaust the domain of responsibility.

Another dimension of responsibility involves the content of the choices and the conditions under which choices or options are made possible. In terms of food, the contents of the choices are quite literally the ingredients. If the industrial food complex is creating more and more of the hyperpalatable foods and these foods have been shown to be potentially as addictive as illegal drugs such as cocaine and heroin and a legal drug such as alcohol, then what responsibility do these food companies bear? This question will make many people uncomfortable since it would appear to indict much of the food industry from the producers and distributors of food products to the grocers who sell these foods. As more hyperpalatable foods are produced and sold at affordable prices, the demand for them will grow, thus diminishing the demand for regular or traditional foods. In the face of declining demand, more space will be allocated for foodstuffs that sell. Thus, there is an appearance of more options on your grocer's shelves due to market segmentation of these hyperpalatable foods, but in reality, choices have constricted when traditional or less highly processed foods disappear.

To many people, conceiving commercial food creators and producers as drug pushers is incendiary and polemical. But if it is granted that certain foods can be addictive because they are hyperpalatable and the research and development divisions of companies are constantly increasing this level of hyperpalatability, then the space to discuss the responsibility that companies bear for the significant monetary and health costs that follow from food addiction needs to be opened. Many argue that this requires more robust accounts of corporate responsibility.

Learning from the Tobacco Industry

Moving concerns about the creation, production, distribution, and consumption of addictive foods into a public health model may be helpful for developing a multiprong approach to lessen the potential health crisis. This was the case with tobacco products. For years, tobacco companies were aware of the addictive qualities of nicotine and the harmful effects of smoking. Tobacco companies used chemical additives to enhance the pleasure of smoking tobacco. In effect, they created hyperpalatable tobacco products. Companies created more products that were aimed at particular demographics in order to cultivate brand loyalty. Prior to 1998, the tobacco industry had won the vast majority of individual lawsuits filed against it because they could claim that smokers chose to smoke knowing the dangers. The Attorney General from the state of Mississippi sued because the state was paying for the healthcare of sick smokers. Soon, the Attorneys General of several states filed suit as well. Ultimately, the industry settled for \$246 billion dollars to be paid out over 25 years to the states. It was also the death knell for Joe Camel and the Marlboro Man in cigarette advertising. Might Tony the Tiger meet a similar fate? Should the estimated healthcare costs even come close to actuality, Attorneys General may find themselves filing suits against many of the giants of the food industry.

Legislation also plays a role in the regulation of tobacco. The cost of tobacco products has increased significantly for at least two reasons. The first is a lack of governmental subsidies and the second is taxation. While the term “vice tax” is problematic, certain products such as cigarettes and alcohol are taxed at higher rates with the hope that expense will keep some people from buying and using the products. At present, corn and sugar, two of the most common ingredients in hyperpalatable foods, receive government subsidies. Government subsidies are always a contentious issue, and these subsidies in particular might be subject to closer scrutiny. Additional taxation on hyperpalatable foods may also be an option.

Advertising is also subject to regulations. Advertising plays an important role in cultivating brand loyalty and building a solid customer base. Joe Camel and the Marlboro Man were the two most readily identified icons of the smoking industry, each having its own product line. Each pack of Camel cigarettes earned the buyer points that he could use to “purchase” Camel products such as tee shirts, hats, and drink cozies. Tobacco advertising now is very strictly regulated and where they do appear, they appear with health warnings. Advertising for hyperpalatable foods may also be subject to more stringent regulation, particularly those products aimed at children.

Consumer education meets nutritional values of foods in the form of labeling on prepared foods (calories fat, fiber, protein, vitamins, number of servings). While the US Food and Drug Administration requires nutrition labels, companies have discretion over the size of a serving. Most consumers are not aware of this fact, assuming that a serving size meets an industry standard. Companies can frame the serving size for their product and then claim, for example, “Only 100 calories per serving.” This “health-framing” is a successful marketing technique, since consumers may pick up two different brands of a product and simply compare calories, not recognizing that the serving sizes vary significantly. A study found that the most nutritionally vigilant consumers were most affected by health-framing, as counterintuitive as that may seem. The hypothesis is that guilt motivates shoppers to select the product advertising the lowest number of fat grams and calories without attending to the number of servings. One recommendation is that the FDA mandates all nutritional information be presented in a standardized way in terms of grams or ounces, for example. Such standardization would make it easier for consumers to compare across products (Mohr et al. 2012). Something similar happened in the alcohol industry in the United States. A standard drink is 12 oz beer, 8 oz malt liquor, 5 oz wine, and 1.5 oz (a shot) or 80 proof distilled liquor. The standardization in principle allows people to more accurately monitor and perhaps moderate consumption.

Federal and state governments singled out children smoking for educational and policy intervention. The same is happening with children's food choices and eating habits. Studies have shown a relationship between first use of alcohol and the likelihood of developing alcoholism (Agrawal et al. 2009). The claim that a similar relationship might hold with food is more contentious, because there seems not to be a food equivalent of "first use" since humans eat from birth. State governments, in response to rising concerns about the health of young people, have become more involved in regulating the types of food available in schools.

California banned the sale of soda drinks from grade schools in 2002 and then later extended that ban to high schools. The state also initiated rules about the nutritional value of foods that students could have at schools, especially what was available in vending machines. A recent study found that California students have the lowest intake levels of sugar, fat, and calories than students in other states (Taber et al. 2012).

Summary

This entry has explored the question whether food like other substances such as alcohol, cocaine, and nicotine can be addictive. An affirmative answer to this question raises important implications for individuals as well as for the population as a whole. Questions of responsibility are addressed both at the level of an individual's consumption of food and at the level of the manufacture of food. Finally, the Tobacco Master Settlement may provide some lessons for a multiprong approach to food addiction.

Introduction

This entry aims to outline major ethical concerns relating to food additives and to identify the consequent trade-related issues. It begins with a brief account of the functional and economic rationales for using food additives in processed foods, proceeds to an identification of the ethical concerns associated with their use, and then examines the ways in which these concerns have been addressed. In conclusion, the entry discusses some implications of the ethical analysis presented for international trade in foods containing additives.

Background

Several thousand different chemicals are currently added to processed food. The use of food additives has been integral to developments in the global food industry over recent decades, which are characterized by terms such as “agribusiness” and “food processing.” In consequence, the traditional links between agricultural raw materials and food products have

been progressively eroded in a process in which farm products are reduced to simple industrial inputs such as proteins, carbohydrates, and fats. These inputs are then reconstituted in “manufactured” foods, which possess many commercial advantages, e.g., longer shelf life, convenience in processing, and standardized composition. As a result, food has become more heterogeneous, with specific products formulated by novel processing techniques that impart the products with “added value,” i.e., they are more commercially profitable.

According to Roberts, “as production has become almost entirely automated, with vegetables diced, meats ground, batters mixed, doughs extruded, and ready-to-serve dinners assembled, all by computer-controlled robots at rates of thousands of units per minute, the food itself has had to be amended, often significantly, to tolerate the process.” The use of additives has thus served to “repair the damage done to the food during manufacturing,” e.g., with artificial colors added to restore those lost in cooking and pulverizing and synthetic flavors used to replace easily damaged natural flavors. Often addition of a single substance, like monosodium glutamate, can substitute for the range of natural flavors of meat without most consumers noticing the difference.

Additives also allow manufacturers to economize on the cost of natural ingredients by avoiding the problem of their frequently limited supply. Moreover, the shelf life of foods can be extended and considerable economic savings made by simplifying the complex procedures involved in cooking. These commercial advantages apply particularly to “fast food.”

Categories of Food Additive

European Community (EC) legislation defines a food additive as “any substance not normally consumed as a food in itself . . . the intentional addition of which to food for a technological purpose . . . results . . . in it or its by-products becoming directly or indirectly a component of such foods.” In the European Union (EU), all additives are assigned E numbers (Table 1).

Food Additives and International Trade,
Table 1 Categories and examples of food additives regulated for use in the EU

E numbers	Category	Examples
100–199	Colorants	Sunset yellow, tartrazine
200–299	Preservatives	Sulfites, benzoates
300–399	Antioxidants, acidity regulators	Ascorbates, phosphates
400–499	Thickeners, stabilizers, emulsifiers	Alginates, natural gums
500–599	Acidity regulators, anticaking agents	Mineral acids and bases
600–699	Flavor enhancers	Glutamates, inosinates
700–999	Miscellaneous	Waxes, cyclamates, saccharine
1000–1999	Additional chemicals	Lipases, ethanol

Some additives are natural substances and others synthetic, but the distinction is blurred when naturally occurring substances are synthesized in the laboratory and might thereby acquire unwelcome contamination. Perhaps more problematical are those additives that are xenobiotics, i.e., substances not normally produced or present in the human body, the metabolism of which might be considered of greater concern for consumers' health.

Millstone and Lang (2008) reported that, in terms of global market share, approx. 40% of additives were used to affect the taste, 30% the texture, and 5% the appearance of food. Nearly 20% served as processing aids, and only about 5% were added for safety reasons to protect consumers from bacterial food poisoning and rapid deterioration of food quality. The latter are crucially important, e.g., in inhibiting the growth of bacteria causing conditions such as botulism, which is a serious form of food poisoning. On average, in industrialized countries, each consumer ingests 7–8 kg of food additives p.a., an amount costing food manufacturers about US\$20.

However, recently, EU regulations on additives have changed to include food flavorings. Formerly, several thousand artificial flavorings were permitted largely according to the same

criterion that the US Food and Drugs Administration (FDA) designated “generally recognized as safe” (GRAS). But EC regulations are currently being amended to establish a common authorization procedure for food additives, food enzymes, and food flavorings.

The term “additive” does not generally apply to substances added to food unintentionally, such as packaging migrants, agrochemicals used in crop production, or drug residues resulting from treatment of farm animals. Although these substances are often matters of ethical concern, neither they nor substances intentionally added to so-called functional foods (Mephram 2011a) are discussed here. Moreover, while not classed as food additives, sugar and salt are also added substantially to many foods, and it is arguable that the resulting adverse public health consequences, e.g., in terms of heart disease and obesity, may be far more serious than for many of the food additives discussed in this chapter.

The vast majority of additives raise few concerns in terms of consumer health, but for a significant number, their use is ethically problematical. According to Millstone and Lang (2008), doubts have been raised about approximately 200 food additives, which are claimed to cause acute intolerance or allergic reactions in certain consumers or to increase the risks of serious long-term harms, such as cancer. Unsurprisingly, such claims result in a significant level of public concern. For example, in the EU, 25% of people surveyed in 2010 were “very worried” about food additives, and a further 41% were “fairly worried” (Eurobarometer 2010) – data that show a significant increase from an equivalent survey in 2005.

In response to these findings, in 2012 it was reported that it was proposed to reevaluate all existing additives with an E number, a task which was planned to be completed by 2020 (European Food Safety Authority 2012).

Regulation of Food Additives in the EU

EU legislation on food additives requires that their use be explicitly authorized, which itself depends on satisfying three conditions (European Commission 2011), viz.:

- There is a technological need for their use.
- Potential consumers are not misled.
- The additive presents no hazard to consumers' health.

Authorization for the sale of foods containing additives is only granted after they have been evaluated for their safety by expert panels, e.g., that advising EFSA. But outside the EU, other regulatory bodies not only define additives differently but also set standards that may differ appreciably from each other, a situation that inevitably complicates matters in a globalized food market.

For the discussion of ethical concerns relating to food additives, reference is here made, in the first instance, to the situation in the EU. The implications for international trade in foods of the different arrangements in other nation states are discussed in a later Section.

Ethical Concerns

Whether the three preconditions for authorization of food additives in the EU, listed above, are always adequately observed is subject to debate. Thus, crucial ethical issues concerning food additives may be classed as:

- Consumer sovereignty, i.e., consumers' ability to act on their informed judgments about additives
- Risks of any harms to consumers' health resulting from additive consumption
- The adequacy (and usually adverse effects on laboratory animals) of mandatory safety evaluation procedures

These issues, with the exception of that concerning effects on laboratory animals (recently addressed by Mephram 2011b), are now discussed in turn.

Consumer Sovereignty

This refers to individuals' status in respect of their informed choices over what they consume, the term implicitly echoing the time-honored maxim

"the consumer is king." It is thus one aspect of the broader concept of autonomy, a vital feature of human rights. In relation to food, there are strong reasons why consumer sovereignty demands explicit respect. Thus, (i) food has the capacity to profoundly affect consumers' well-being, positively or negatively; (ii) any effects may not be evident until a food has been consumed for a long period (e.g., over many years); (iii) sensory inspection is not always a reliable means of assessing food safety; and (iv) the complex ways nutrition interacts with other factors, such as individual genetic predispositions or lifestyles, coupled with the low precision with which outcomes can be forecast, mean that informed food choices are intrinsically difficult.

Currently, many widely consumed foods contain several food additives, which it is necessary to assess in the context of consumer sovereignty. Three ethical principles are customarily taken to define consumer sovereignty, viz., the target consumer should have:

- The capability of understanding the product and any associated risks
- A choice of goods, provided by competition
- Sufficient information to judge how expectations of the goods are satisfied

Whether these principles are adequately respected spans a range from, at one extreme, a familiar, naturally occurring, additive raising no safety concerns to, at the other extreme, a case in which the additive is an unfamiliar, synthetic chemical, and employed, e.g., to give the food a vivid color.

But many consumers are often not in a position to make sound decisions on such matters. This is because food preparation and distribution in the form of prepared meals often deny them realistic opportunities of making informed choices. Arguably in such cases, consumers might be said to forfeit their autonomy. But an alternative interpretation is that their autonomous actions involve placing trust in the regulatory bodies that governments invest with the authority to adjudicate on food safety. The crucial question then becomes whether the trust demonstrated is justified by the trustworthiness of the appointed trustees.

Several factors affect trustworthiness. Notably, consumers' opinions depend on perceptions of the competence and motivation of regulatory authorities. But large numbers of other individuals are also involved in ensuring food safety, e.g., scientists and technicians performing tests on laboratory animals and administrative staff responsible for collating results. The evidence obtained is then subject to the judgments of government advisory committees pronouncing on acceptable safety standards, the accuracy of quality control procedures in food manufacturing establishments, and the effectiveness of trading standards officers in monitoring international transactions. Skeptical consumers might perhaps question the intrinsic instability of such long chains of responsibility.

Arguably, the central problem of consumer trust is one of the trustworthiness of regulatory authorities, and recent history has unfortunately provided numerous examples in which they have fallen short of consumers' expectations. Thus, before the link with new variant Creutzfeldt-Jakob disease (nvCJD) in some British consumers was established, there were repeated governmental assertions that beef from BSE-infected cattle (i.e., with bovine spongiform encephalopathy) was safe for human consumption. And globally, there have been many other reports of defective food safety regulation. Hence, the public trust sought by the policy-makers (the trustees) will only be achieved when trustworthiness is *won*: people cannot simply *decide* to trust others.

These difficulties are undoubtedly compounded by the effects of food advertising. For example, the Yale Rudd Center estimated that \$4.2 billion was spent in 2009 on fast-food advertising in the USA, an amount vastly exceeding the \$6.5 million budget of the USDA's (United States Department of Agriculture) Center for Nutrition Policy and Promotion – the remit of which is to “improve the health and well-being of Americans by developing and promoting dietary guidance” (Harris et al. 2010). Given the enormous disparity in financial investments, the authenticity of the concept of consumer sovereignty must surely be questionable.

In summary, critical ethical issues concern (a) the extent to which all consumers are able to make, and act on, sound judgments concerning

the safety and acceptability of food and (b) the perceived trustworthiness of regulatory authorities and of the many components of the food supply chain.

Risks of Harm to Consumers

Claims have been made that additives are directly responsible for a wide range of disease conditions. Although some alleged associations are probably ill-founded, there seems to be strong *prima facie* evidence for certain claims. Several public interest groups have drawn up lists of additives they consider should generally be avoided or treated with caution, especially by sensitive individuals, e.g., the US Center for Science in the Public Interest.

In theory, safety assessments of food additives might be based on two types of evidence, viz., epidemiological data and results of toxicological tests. In practice, because of the complexity of people's diets, lifestyles, and genetic predispositions, it is only rarely possible to derive useful data from epidemiological studies. Exceptions to this generalization almost prove the rule. For example, acute adverse reactions to foods known to contain certain substances (as in the rapid onset of asthma attacks or other allergic reactions to certain colorants) may be strongly suggestive of causal links.

Acute Effects

Ben Feingold, a Californian pediatric allergist, proposed in the 1970s that certain artificial colors and flavors cause hyperactivity in children, now classed as “attention deficit hyperactivity disorder” (ADHD). His recommended additive-free diets found support from many, but were often disparaged by mainstream medical practitioners.

Recently, more substantial evidence for such neurotoxic effects has been provided, notably by a dietary intervention study funded by the UK Food Standards Agency (FSA). The study involved healthy children who received fruit drinks containing various levels of six colorants and one preservative additive. The authors concluded that, in contrast to consumption of placebos,

“artificial colours or a sodium benzoate preservative (or both) in the diet result in increased hyperactivity in 3-year-old and 8/9-year-old children in the general population” (McCann et al. 2007). The colorant additives identified as potential causal factors in ADHD responses were sunset yellow (E110), quinoline yellow (E104), carmoisine (E122), allura red (E129), tartrazine (E102), and ponceau 4R (E124).

Consequently, the FSA recommended that manufacturers and retailers find alternatives and that carers avoid them if concerned about their children’s behavior. Although, initially, the EFSA was skeptical, after performing a reevaluation of several sets of data, the recommended acceptable daily intakes (ADI) of E104, E110, and E124 have now been reduced (European Food Safety Authority 2010).

Soft drinks are also the subject of much concern because there is recent neurophysiological evidence that, in addition to their neurotoxicity, additives can become addictive (Gearhardt et al. 2011), which might well be a critical factor in the rapidly increasing incidence of obesity that is evident worldwide.

Chronic Effects

If establishing causal factors of acute effects is problematical, doing so for chronic effects is usually even more difficult, and the intrinsic imprecision of many evaluations is compounded by the fact that tests on individual additives take no account of synergies with other additives and dietary components. Consequently, there is an almost complete reliance on toxicological studies on animals to provide quantitative evidence.

The Delaney Clause, introduced into US food safety legislature in 1958, which stipulated that “no additive shall be deemed to be safe if it is found to induce cancer when ingested by man or animal,” has been a matter of contention ever since. In part, this is because it is now realized that virtually any chemical, even at a low level of exposure, might prove carcinogenic in some individuals. But, in practice, the *de minimis* principle is now often applied, whereby a risk of less than one in one million is considered negligible.

However, a recent illustration of the possible relevance of animal studies is the report that high dietary inorganic phosphate (Pi) levels in mice stimulate tumorigenesis by influencing the activity of pivotal genes for lung cancer (Jin et al. 2009). These appear to be important findings, firstly because this condition has the highest global mortality rate of all cancers and secondly, because between 1983 and 1993 there was a 17% increase in addition of Pi to processed foods (e.g., meats and cheeses) to increase water retention and texture – a trend that seems likely to continue.

In fact, a large number of other food additives (or their metabolites) have also been alleged to be potential carcinogens in humans, including sweeteners (like saccharine, cyclamates, and aspartame), xenobiotic colorants (including the six listed above), and preservatives (such as nitrates and nitrites, which by reacting with amino acids form carcinogenic nitrosamines) (Rock et al. 2000).

Risk Assessment

The standard approach to addressing the safety of chemical hazards comprises four elements: (i) hazard identification, (ii) risk assessment, (iii) risk management, and (iv) risk communication. Historically, the elements were thought to provide a necessary separation between the scientific domain (i and ii) and the policy-makers’ domain (iii and iv), thus leaving politicians with the task of managing the policy implications of the, allegedly objective, facts the scientists produce.

Accepting the insight of Paracelsus (dubbed “the father of toxicology”) that everything is a *potential* poison – the dose being the crucial factor – means that risk assessment is a major concern, on which subsequent elements are highly dependent. However, the body reacts to ingestion of a chemical in diverse ways. Thus, toxicokinetic studies reveal that different dose levels can produce varying responses in factors such as stability, solubility, absorption, protein binding, and metabolism – which may elicit markedly different end results. Moreover, there are serious concerns over whether, in extrapolating from results of animal tests, the arbitrary safety factor of

100 (expressed per kg body weight) is always adequate (Mephram 2011b).

Defined as “the probability of harm,” the significance of risk is most meaningfully expressed as the product of probability and severity, but other relevant features include the intensity, duration, and reversibility of the harm. An important consideration is the manner in which scientific assessments of risk are employed in circumstances in which legal criteria might be more appropriate. For example, it is generally accepted that in law, it would be a more grievous error to convict one innocent person of a serious crime than to acquit ten guilty persons. Yet scientific standards insist that a causal relationship between a chemical agent and human mortality requires that the odds be, at least, reversed. Arguably, with respect of the burden of proof, the current situation for the safety evaluation of additives should accord much more with the legal approach (e.g., see Cranor 2005).

Moreover, the traditionally acknowledged distinctions between risk assessment, management, and communication are open to severe criticism. While risk assessment is generally considered an objective process that necessarily entails the rigorous application of scientific methods and probability theory, the resulting recommendations are rarely indisputable. This is because risk assessment is far from being value free. Rather, the experts who produce the data for the risk analysis are constrained by the framing assumptions of their enquiries, which include the types of question addressed and those neglected, the evidence considered relevant and that discounted, and the way the evidence is interpreted. These assumptions might seriously affect (a) the reliability of extrapolating from results of short-term tests on laboratory animals to conditions in which people consume food in the real world, (b) the time and resource investments considered appropriate for adequate testing, and (c) the skills, experience, and presumptions of the experts chosen to make policy recommendations.

At issue here is the appropriate application of the precautionary principle, which states that lack of scientific certainty should not be used as a reason to ignore or postpone preventive or remedial action when there are other good reasons to

do so, i.e., the principle aims to address the problems of uncertainty. The sheer complexity of the cocktail effect of a wide range of diverse individuals consuming inter alia numerous food additives exemplifies the latter factor.

In summary, the critical ethical issue relating to human health concerns the effectiveness of risk assessment and management procedures employed in evaluating the safety of food additives.

Trade-Related Issues

Having surveyed the ethical concerns raised by food additives, it is now appropriate to consider, albeit briefly, the ways these issues are addressed in relation to international trade. The body established to develop global harmonization of standards for international food trade, e.g., by using an International Numbering System for Food Additives (INS), is the Codex Alimentarius Commission (CAC), which is advised by the Joint Expert Committee on Food Additives (JECFA). The latter, a joint World Health Organization and Food and Agriculture Organization (WHO/FAO) body, established in 1956, aims to provide reliable and independent expert advice and thereby contribute to the setting of standards on a global scale for the health protection of food consumers and for ensuring fair practices in the trade in safe food.

The main objectives of CAC’s General Standards for Food Additives (GSFA) are to stipulate conditions in which additives may be used in foods and to establish maximum levels for their inclusion to ensure that the intake of an additive from all its uses does not exceed its ADI.

In adjudicating on international trade disputes, the World Trade Organization (WTO) implements its Sanitary and Phytosanitary Agreement (SPS). Under the terms of the SPS, risk-based standards established by CAC are employed, which in practice rely on judgments documented in the GSFA. The standards are also used in contracts between private companies. However, questions of justice may arise when considering prospective food imports from a less developed country, which has not yet established a fully harmonized food regulatory system.

Traditionally, the CAC operates by consensus, a practice that is not conducive to achieving common global standards in some controversial areas (Paarlberg 2010). For example, the CAC has approved use of several additives (e.g., aspartame), the safety of which remains strongly contested by the governments of some states. Moreover, the number of an additive in the INS list does not necessarily correspond to its E number, while some countries, including the USA, do not use the INS. Thus, despite the goal of a globally harmonized system, this aspiration is by no means yet realized.

Summary

The aim of this review has been to examine food additives from a perspective that prioritizes concern for key ethical principles. Thus, the central issues concern the alleged “technological need” for additive use, the degrees of consumer safety and sovereignty that can be guaranteed, and the reliability of the current mandatory toxicity tests.

Arguably, the analysis presented suggests there is a strong case for significant changes in food manufacturers’ employment of certain food additives, in the levels of precaution adopted in their legal authorization, and in the reliance placed on, and conduct of, tests performed on animals. Implementation of changes based on these ethical considerations would seem certain to have important implications for the regulation of international trade in processed foods.

Food and beverage marketing directed toward children

Introduction

This entry examines the policy debate on food and beverage advertising directed toward children. In particular, we address a number of normative issues for public health policy intervention. We also consider gender dimensions of this policy debate, which have been underexamined.

Key Terms

We begin with a brief discussion of key terms: marketing versus advertising, food and beverages, and directed toward children.

The terms advertising and marketing are often used interchangeably in discussion of this policy issue. Marketing is generally understood as encompassing a broader range of issues, including the “four Ps” of traditional marketing practice: product, price, placement, and promotion. The term advertising usually refers to the promotional component of marketing. In this entry, we refer to the two somewhat interchangeably, with the understanding that broad marketing is likely the more appropriate way to consider a suite of policy interventions as well as related health and policy impacts.

Likewise, many actors would refer to food advertising as the colloquial way to refer to promotion of both food and beverages. The inclusion of beverages in what constitutes “food” has a public health significance and is also rooted in relevant jurisprudence. Beverages have received increasing attention as a significant contributor to the rise in prevalence of obesity, particularly sugar-sweetened beverages (SSBs) as an energy-dense, nutrient-poor food. This has led to public health policy interventions to limit SSB consumption among children, such as in school or recreation facility settings. Other policy proposals addressing SSBs include the widely publicized and failed proposal to reduce the largest beverage size permitted to be served in fast-food restaurants in New York City, which was sometimes referred to as a soda “ban” (the concept of public health “bans” is discussed further below). Finally, beverages are usually considered “food” in

overarching legislation. For example, the US *Food, Drug, and Cosmetic Act* (c. 9, s. II, Sec. 321(2)(f)) notes that “The term ‘food’ means (1) articles used for food or drink for man or other animals, (2) chewing gum, and (3) articles used for components of any such article.” Similarly, Canada’s *Food and Drugs Act* (R.S.C. 1985, c. F-27, Sec. 2) notes that “‘food’ includes any article manufactured, sold or represented for use as food or drink for human beings, chewing gum, and any ingredient that may be mixed with food for any purpose whatever.”

A key phrase is “directed toward children.” The dominance of food industry self-regulatory approaches to governing food advertising has meant a great deal of dispute over what constitutes advertising that is specifically directed toward children with the intent to influence their personal consumption, versus advertising that is directed to gatekeeper adults such as mothers, or part of the general social environment in which children happen to be (also discussed further below).

Overview of the Policy Issue in Health Terms

Policy debate on food advertising to children is not new, having been part of concerns about commercial influence in society for several decades. The current imperative for intervening through public policy is principally justified in terms of the need to address evidence about adverse health and dietary impacts of marketing, among a generation of children whose life expectancy is now less than their parents.

The major global systematic reviews on the health effects of food advertising directed toward children have been the Hastings et al. (2003) review, conducted by a group in the United Kingdom and subsequently updated for the World Health Organization (2007, 2009), and the US Institute of Medicine’s (2006) report. These reveal that children are exposed to a greater intensity and frequency of advertising than ever before, including food and beverages that are predominantly energy dense and nutrient poor. The balance of evidence also indicates that advertising

influences childhood food preferences, knowledge, dietary choices, and health status. The most prominent effect appears to be on consumption (purchasing) behavior.

Policy actors worldwide have promoted three general types of strategies in terms of policy interventions to limit the negative influences of advertising on child health and well-being and/or ethical marketing (WHO 2010, 2012). The vast majority of jurisdictions have undertaken “voluntary” approaches, i.e., food industry self-regulation in the form of standards for ethical advertising practice. Several food industry and marketing industry associations worldwide have led initiatives to adopt “pledges” to alter their practices, although critics have often argued that such voluntary activity has not been sufficient to substantively alter the food advertising environment.

The “ban” or comprehensive public policy approach uses statutory regulation to limit childhood advertising exposure, although these vary from “total ad bans” (all commercial advertising) to “food ad bans” to “junk food ad bans” (also referred to as “nutrient-based” approaches) which require definition of what constitutes healthy and unhealthy food. Other jurisdictions have undertaken “stepwise” approaches that target exposures to specific types of products, in particular venues such as schools, or forms of marketing/media such as children’s television programs.

Normative Issues Arising in the Policy Debate

The public health policy discussion on food advertising to children has raised a number of normative issues. We introduce a number of prominent points here, although this is by no means intended to be an exhaustive overview.

One core set of issues asks about the role and value of advertising in society. The purpose of advertising is to promote consumption, which ostensibly is a generic market instrument that could be applied to different types of goods and services, useful, beneficial, pleasurable, and/or harmful alike. The concepts of ethical

consumption, marketing ethics, ethical advertising, and social marketing suggest that advertising is not inherently harmful, and can offer value in human life. The concept of corporate social responsibility (CSR), which has recently been updated to a notion of creating shared value (CSV), suggests that for-profit companies have social contributions to make and, also, that they are valid and important actors in societal decision-making, e.g., in the public policy domain.

A contrasting view would suggest that advertising is inherently manipulative, particularly in the presence of advancements in marketing practices based on psychological and neurological research, which include techniques aimed at shifting the subconscious. In this case, the capacity of individuals – even adults – to act freely on market incentives comes under question. The body of consumer behavior research on “mindless eating” (e.g., Wansink 2004, 2006, 2010) suggests that social and environmental cues such as large portion sizes and among advertising techniques, health claims, prompt people to eat more than they need, leading to caloric overconsumption, and more than they would if they were to choose freely without the influence of those cues. In this case, public policy intervention is deemed necessary to correct market failure in the form of information asymmetry, a lack of full and appropriate inputs for consumer decision-making.

A second set of issues speaks to the question of advertising specifically directed toward children. One dimension is about the group characteristics of children, who are generally seen as vulnerable in contrast to adults and requiring a broader range of societal protections. Another dimension, however, is to consider exactly how advertising relates to its potential audiences. Even if advertising is not inherently harmful, some would suggest that it is intended to appeal to abstract reasoning (e.g., desirability of a product) versus more concrete concerns such as material need or price. As noted above, one of the shifts in marketing practice over time has been to appeal to increasingly abstract dimensions of the relationship between people and products, such as the development of a lifelong emotional bond to a brand (sometimes referred to in child-directed marketing as “cradle-

to-grave” marketing). As such, the argument might proceed that those who lack sufficient cognitive capacity to fully comprehend the persuasive intent of marketing should not be targeted by it. One practical definition of relevant cognitive capacity in childhood that has been used in policy debate is Piaget’s cognitive stages.

A third set of issues examines the specific harms associated with advertising directed toward children. Policy proposals have largely been put forward on the basis of a range of health effects of advertising directed toward children, introduced in the section above. The overarching rationale for policy intervention that policymakers have been most interested in, however, is the health outcome of childhood obesity. Restrictions on food and beverage marketing are seen as an effective policy instrument to stem the rising tide of obesity among children at the population level, with the reasoning that shifts in marketing over time have been a key etiologic factor. The focus on obesity has attracted particular attention amidst growing concern about future health-care costs associated with obesity and its sequelae, a utilitarian perspective. Yet some policy actors would argue that an obesity focus does not take into account the broader range of potential harms to children that would be important to air in public discourse about marketing in society. The section on gender dimensions below offers examples of some of these potential harms.

A fourth group of issues, discussed in some detail under other encyclopedia entries, is about the agency of children and whether children are (policy or market) actors in their own right. On the one hand, this line of argument comes from the concept of the rights of the child and the responsibility of states to uphold this right. The field of child-targeted marketing, however, also views children as important independent actors, either as shoppers directly making purchases or as indirect influencers of consumption, such as in the concept of the “nag factor” (where the purpose of marketing is to promote children’s persuasion of adults who shop for them) or the “four-eyed, four-legged superconsumer” (where the child and mother make up a single super-unit that is the target of marketing practices).
